

# **Proof of Concept Technical Solution**

## for the *Marconi Law Firm, LLC.*

## (WordPress Website)

**Project Background:** Assume that you are an entrepreneur and that you own your own Information Technology (IT) consulting firm. You have recently acquired a new client called “Marconi Law Firm”. As part of your client’s contract agreement, you are to deliver full documentation for their upcoming WordPress Website Hosting project implementation. This documentation includes a Proof-of-Concept Technical Solution which documents all software, hardware, and network configuration details. Assume that the finished document will be used in-house by the Marconi Law Firm and will be referenced by their in-house IT department---after the project has been successfully completed.

Humberto Gonzalez

IT & Cybersecurity Solutions

# Preface

This document will serve as proof of concept to Mr. Marconi for creating his WordPress website for his law firm and as audit documentation.

The purpose of audit documentation is to provide a comprehensive record of the organization's information technology infrastructure and security controls and processes. It plays a crucial role in providing transparency, accountability, and QA/QC regarding an organization's cybersecurity controls and practices. It enables organizations to demonstrate compliance, identify areas for improvement, and make informed decisions to strengthen their overall organizational cybersecurity.

## Audit documentation serves several important purposes:

- **Compliance:** Evidence that an organization has undergone a thorough examination of its systems. It helps validate that the organization has implemented appropriate controls to protect its information systems and sensitive data.
- **Validation:** Verification of the effectiveness and adequacy of cybersecurity controls. It provides detailed information about the design, implementation, and operation of these controls, enabling reviewers to assess their reliability and identify any gaps or weaknesses.
- **Records Maintenance:** Historical record of cybersecurity audits conducted over time. It enables organizations to track their progress, identify trends, and evaluate the effectiveness actions taken. It also serves as reference for future audits and allows auditors to understand the current cybersecurity implemented and facilitates a more targeted approach to future cybersecurity updates and audits.
- **Decision-making Support:** Valuable insights and information that can support decision-making processes. It allows management to make informed decisions about allocating resources, prioritizing cybersecurity investments, and addressing identified risks and vulnerabilities.

# Marconi Law Network Topology Diagram

Humberto Gonzalez

**X PROXMOX** Virtual Environment 7.4-3

Made with  
**Visual Paradigm**  
For non-commercial use

## Summary for Topology

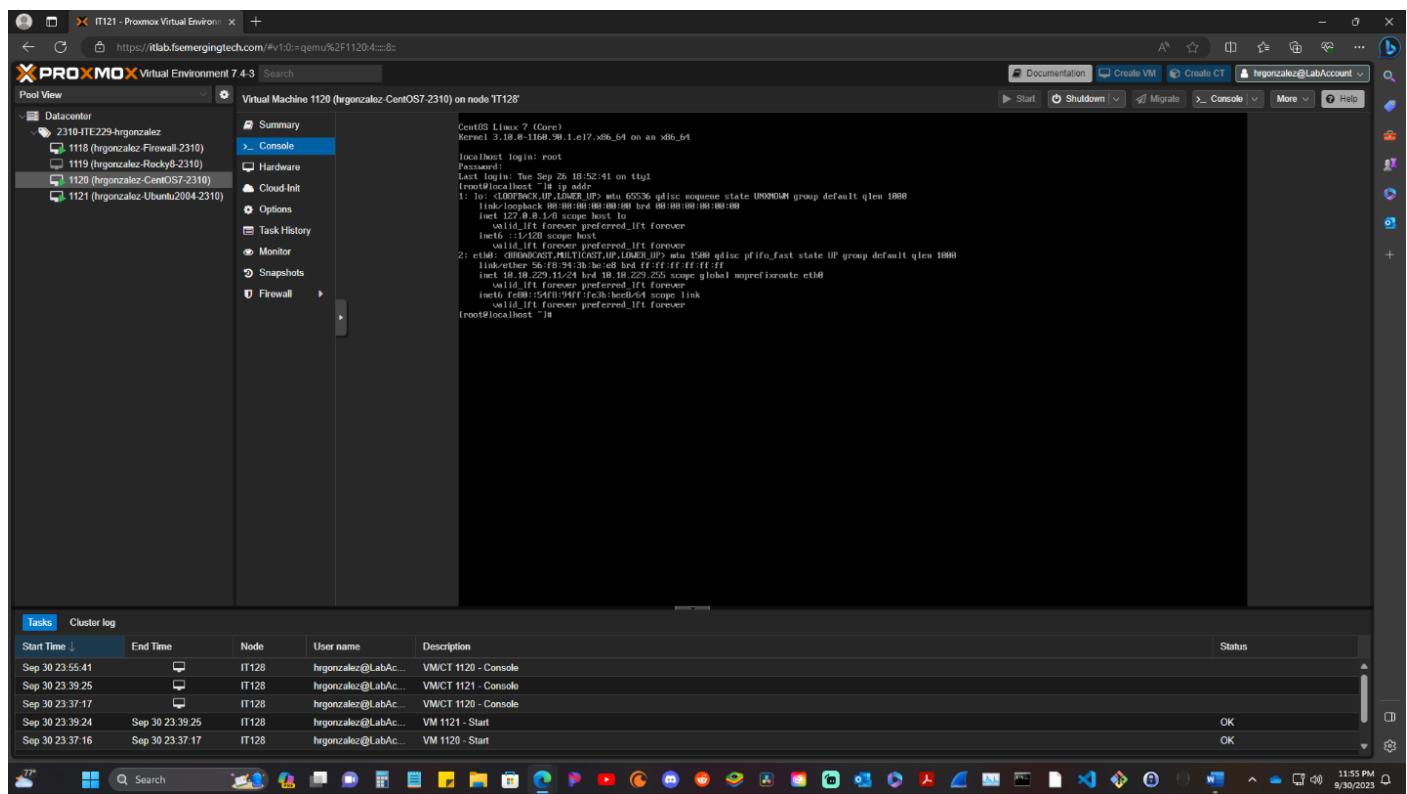

In summary, Nginx serves as a reverse proxy that directs incoming web traffic to the appropriate container (in this case, the Ghost container) based on the requested domain path. The Ghost container evaluates the request, collects data from a database if necessary, and prepares the HTML response, which is then transmitted back to the user's browser for rendering via Nginx. This configuration offers web application hosting flexibility, scalability, and security.

Adding LAMP Stack to the topology changes things a bit from previous setup. Nginx will operate as a central traffic director like usual, selecting which back end (WordPress or Ghost) should handle incoming requests based on the URL or domain. Docker is utilized to isolate and manage the Ghost containers, while the LAMP stack (Apache, PHP, and MySQL) handles WordPress site requests. This infrastructure enables different websites and services to be hosted in the same environment, while maintaining it's flexibility, scalability, and security.

# Node.js Application (Ghost) on Docker

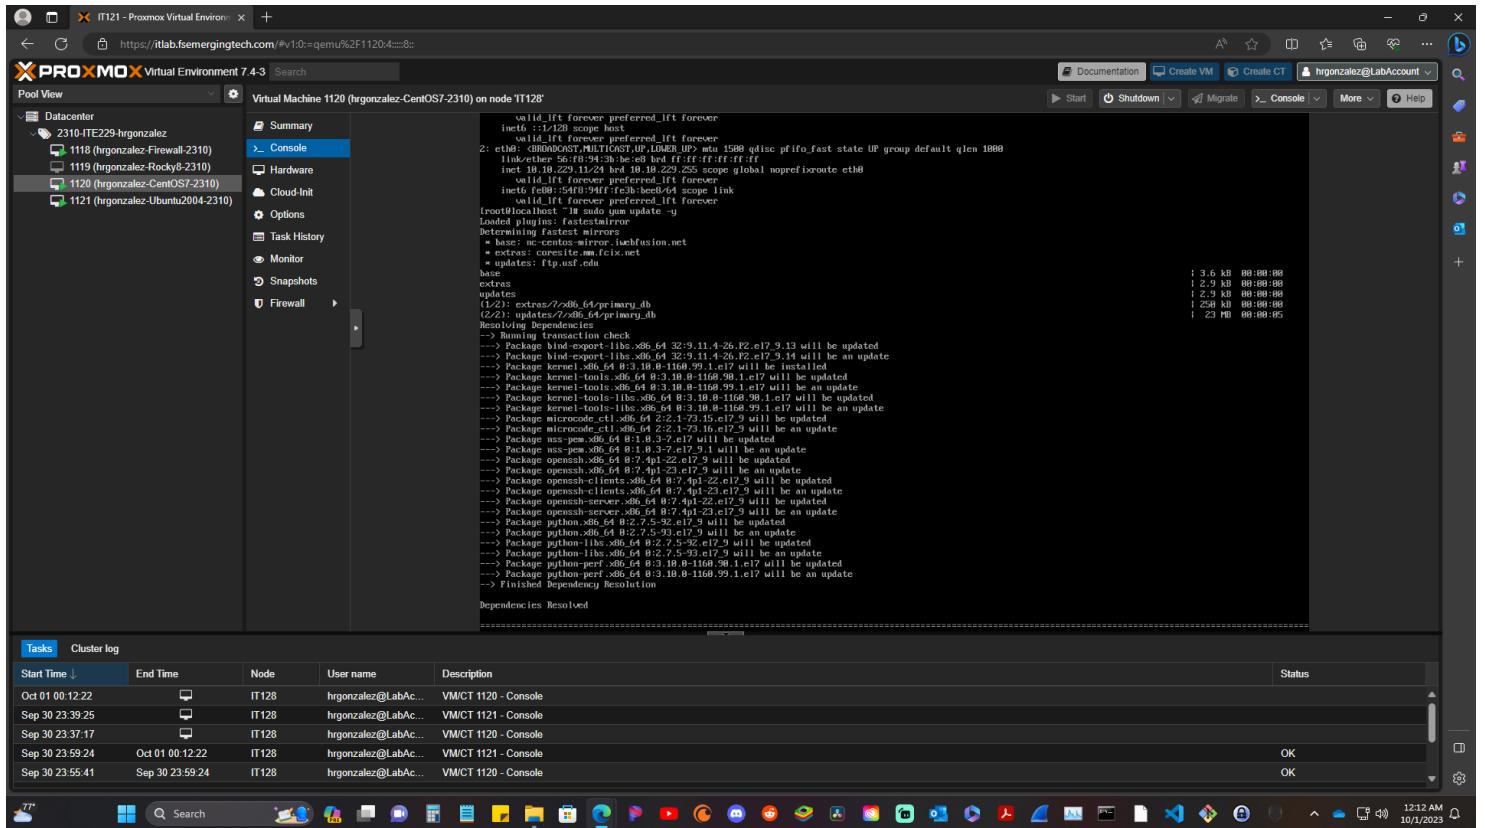

Show screenshot of your CentOS 7 Console in VE

Open CentOS 7 and log in as **root** w/password **Fullsail1!** In the terminal window verify IP Address by entering command prompt **ip addr** and make sure the ip address is **10.10.229.11/24**

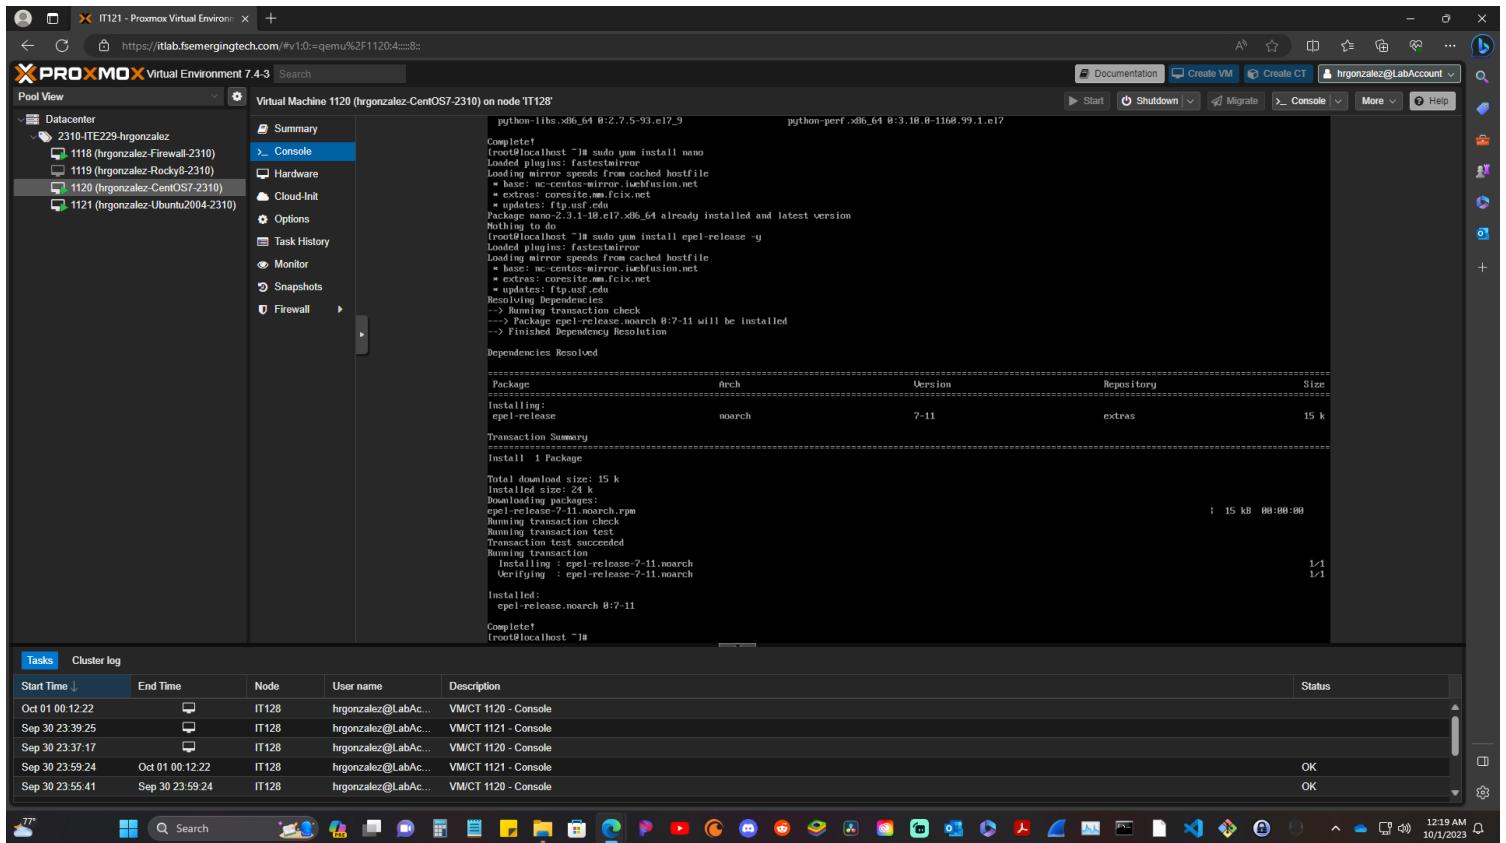

## Update CentOS

Next make sure you are using all the current updates and files by entering the command prompt **sudo yum update -y**

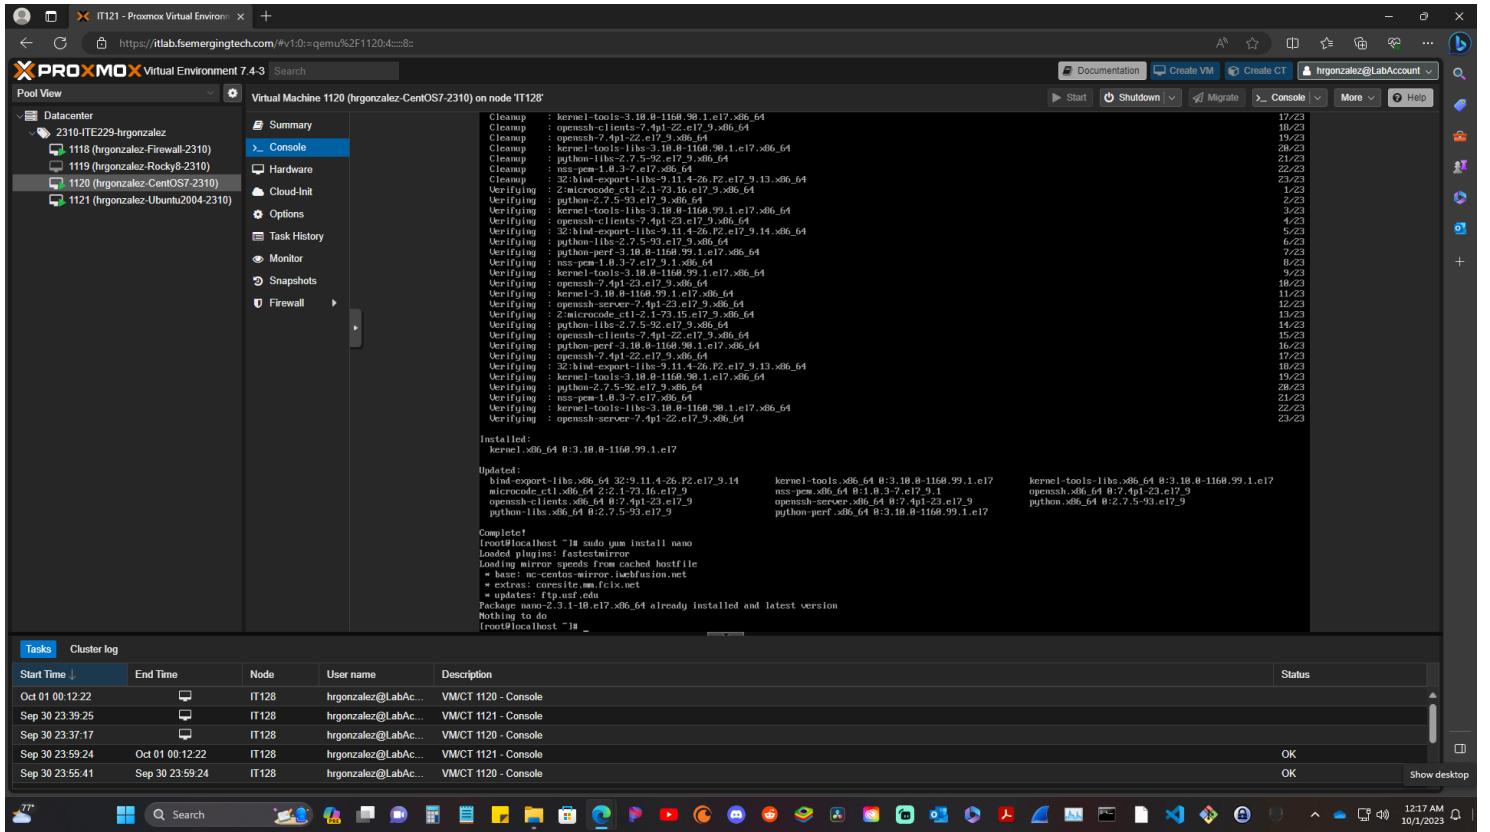

## Install EPEL Packages

Install all the extra packages for enterprise Linux (EPEL) by inputting the command prompt **sudo yum install epel-release -y**

## Install Nano Editor

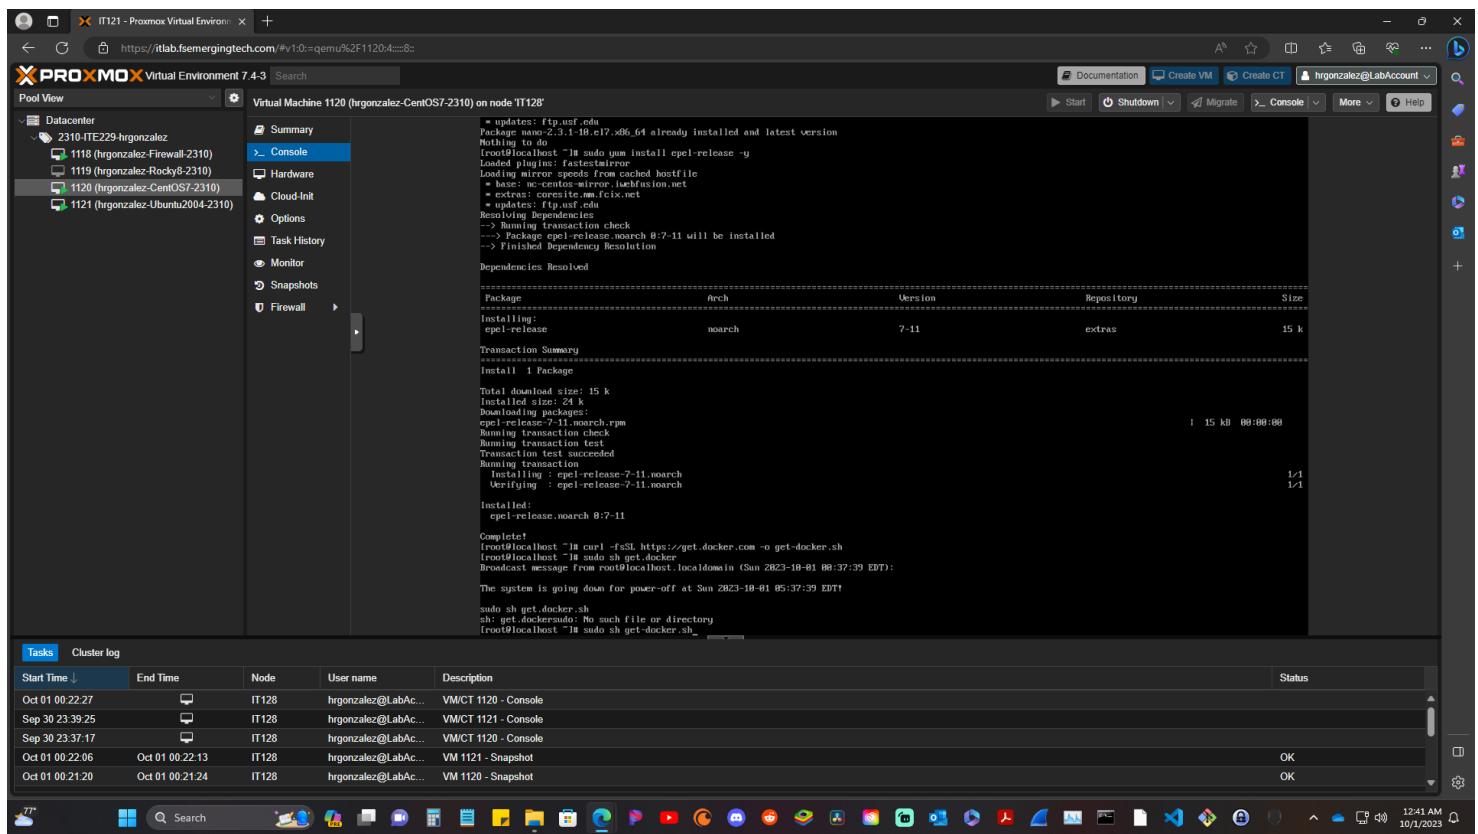

Next, we need to install nano editor. In the terminal window input command prompt `sudo yum install nano`

## Docker CE

### Install required packages

Now that we have all the prequesites is time to install docker and it's packages. In the terminal window input command prompt `curl -fsSL https://get.docker.com -o get-docker.sh` exactly as typed. This will grab the file from is corresponding url without having to externally get it from the webpage itself. If prompted correctly nothing should happen besides returnig you back to your root name.

The screenshot shows a Proxmox Virtual Environment interface with a terminal window open. The terminal window displays the following log output:

```
* updates: ftp.usf.edu
Nothing to do
[root@localhost ~]# sudo yum install epel-release -y
Loaded plugins: fastestmirror
Loading mirror speeds from cached hostfile
  * base: nc-centos.mirror.iwebfusion.net
  * extras: coreite.mirror.fcix.net
  * updates: ftp.usf.edu
Resolving Dependencies
--> Running transaction check

=====
To run Docker as a non-privileged user, consider setting up the
Docker daemon in rootless mode for your user:
    dockerd-rootless-setup.sh install
Visit https://docs.docker.com/go/rootless/ to learn about rootless mode.

To run the Docker daemon as a fully privileged service, but granting non-root
users access, refer to https://docs.docker.com/go/damnon-access/
WARNING: access to the remote API on a privileged Docker daemon is equivalent
          to root access on the host. Refer to the 'Docker daemon attack surface'
          documentation for details: https://docs.docker.com/go/attack-surface/

## Install Docker CE

To install Docker CE input prompt **sudo sh get-docker.sh**

The screenshot shows a Proxmox Virtual Environment 7.4-3 interface. On the left, the 'Pool View' sidebar lists several virtual machines: 2310-ITE229-hrgonzalez, 1118 (hrgonzalez-Firewall-2310), 1119 (hrgonzalez-Rocky8-2310), 1120 (hrgonzalez-CentOS7-2310), and 1121 (hrgonzalez-Ubuntu2004-2310). The 'Console' tab is selected in the center navigation bar. The main window displays a terminal session for VM 1120. The logs show the execution of the command `sudo sh get-docker.sh`. The output includes:

```
* updates: ftp.usf.edu
Package epel-7-11.noarch already installed and latest version
Nothing to do
[root@localhost ~]# sudo yum install epel-release -y
Loaded plugins: fastestmirror

```

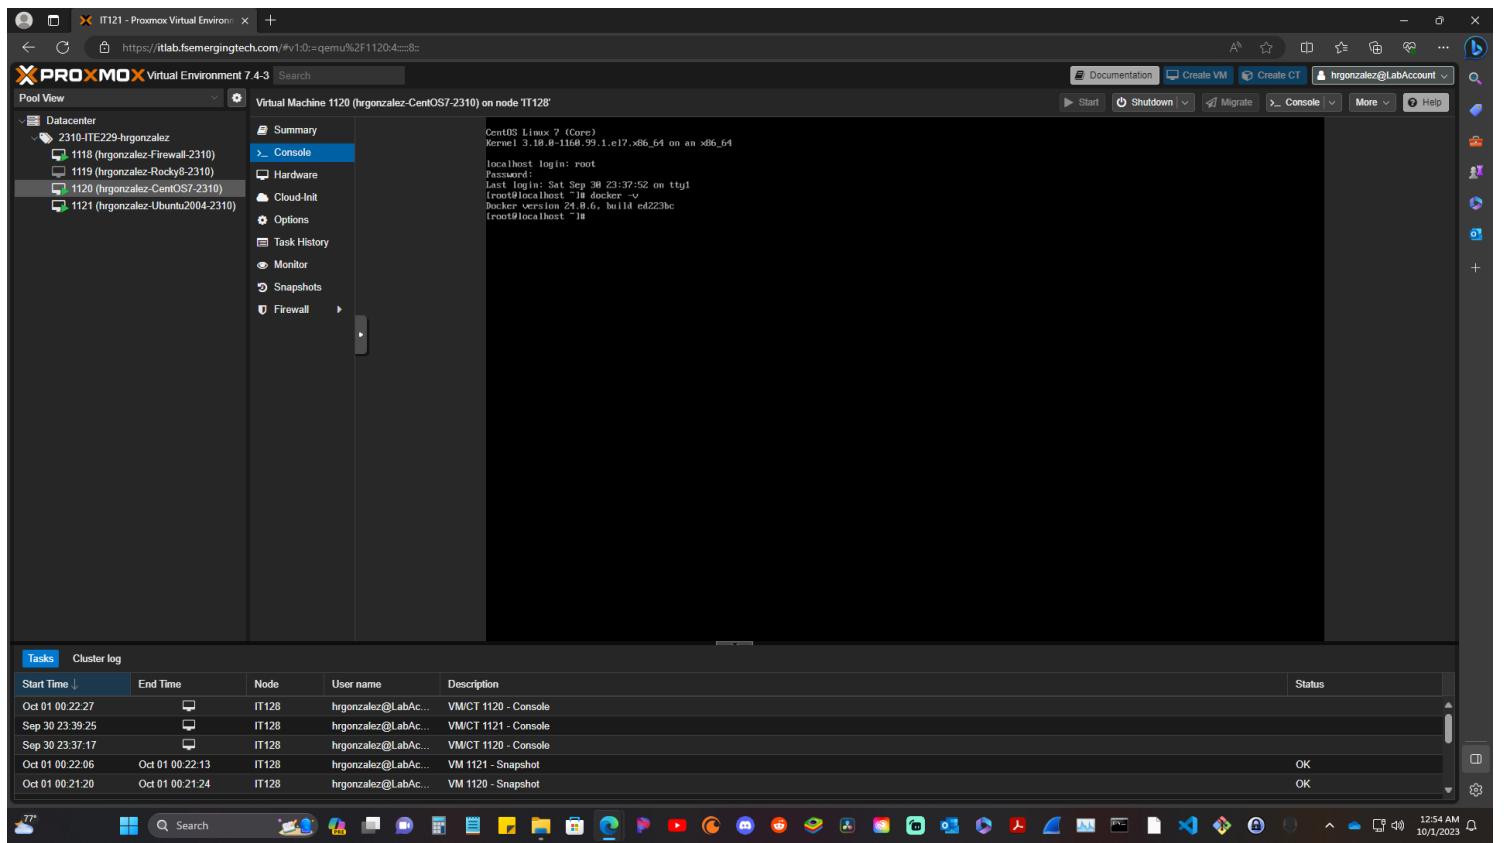

Below the terminal, a 'Tasks' table shows recent activities:

Start Time	End Time	Node	User name	Description	Status
Oct 01 00:22:27		IT128	hrgonzalez@LabAc...	VM/CT 1120 - Console	
Sep 30 23:39:25		IT128	hrgonzalez@LabAc...	VM/CT 1121 - Console	
Sep 30 23:37:17		IT128	hrgonzalez@LabAc...	VM/CT 1120 - Console	
Oct 01 00:22:06	Oct 01 00:22:13	IT128	hrgonzalez@LabAc...	VM 1121 - Snapshot	OK
Oct 01 00:21:20	Oct 01 00:21:24	IT128	hrgonzalez@LabAc...	VM 1120 - Snapshot	OK

The bottom of the screen shows a Windows-style taskbar with various icons.

## Verify docker version

Next we have to verify Docker version by inputting command prompt `docker -v`

## Start Docker

Our next step is to Start Docker service, by using command prompt `service docker start` if prompted correctly it should redirect you to bin/system like in the picture below.

The screenshot shows the Proxmox Virtual Environment 7.4-3 interface. On the left, the Datacenter tree includes nodes IT121 and IT122. The main window displays the console session for VM 1120 (hrgonzalez-CentOS7-2310) on node IT122. The terminal output shows the installation of Docker CE Stable, including the creation of a metadata cache and the configuration of the Docker daemon in rootless mode. The cluster log table at the bottom shows recent events for both nodes.

Start Time	End Time	Node	User name	Description	Status
Oct 01 00:22:27		IT128	hrgonzalez@LabAc...	VM/CT 1120 - Console	
Sep 30 23:39:25		IT128	hrgonzalez@LabAc...	VM/CT 1121 - Console	
Sep 30 23:37:17		IT128	hrgonzalez@LabAc...	VM/CT 1120 - Console	
Oct 01 00:22:06	Oct 01 00:22:13	IT128	hrgonzalez@LabAc...	VM 1121 - Snapshot	OK
Oct 01 00:21:20	Oct 01 00:21:24	IT128	hrgonzalez@LabAc...	VM 1120 - Snapshot	OK

## Enable Docker

Continuing we have to enable Docker by using command prompt `systemctl enable docker` if prompted correctly it should follow by a line which say created symlink like in the photo below.

The screenshot shows a Proxmox Virtual Environment 7.4-3 interface. On the left, the Datacenter pane lists several virtual machines: 1118 (hrgonzalez-Firewall-2310), 1119 (hrgonzalez-Rocky-2310), 1120 (hrgonzalez-CentOS7-2310), and 1121 (hrgonzalez-Ubuntu2004-2310). The central pane displays a terminal window with the following Docker logs:

```
Userid : "Docker Release (CE rpm) <docker@docker.com>"  
Fingerprint: 86fa 61c5 1b55 6a7f 72fa c52f cb6b 621c 9f35  
From : https://download.docker.com/linux/centos/gpg  
=====  
To run Docker as a non-privileged user, consider setting up the  
Docker daemon in rootless mode for your user:  
    dockerd-rootless-setup.sh install  
Visit https://docs.docker.com/go/rootless/ to learn about rootless mode.

Below the terminal, a table titled "Cluster log" shows tasks and events:

Start Time	End Time	Node	User name	Description	Status
Oct 01 00:22:27		IT128	hrgonzalez@LabAc...	VMCT 1120 - Console	
Sep 30 23:39:25		IT128	hrgonzalez@LabAc...	VMCT 1121 - Console	
Sep 30 23:37:17		IT128	hrgonzalez@LabAc...	VMCT 1120 - Console	
Oct 01 00:22:06	Oct 01 00:22:13	IT128	hrgonzalez@LabAc...	VM 1121 - Snapshot	OK
Oct 01 00:21:20	Oct 01 00:21:24	IT128	hrgonzalez@LabAc...	VM 1120 - Snapshot	OK

The bottom of the screen shows a Windows taskbar with various icons and the date/time: 10/1/2023 12:50 AM.

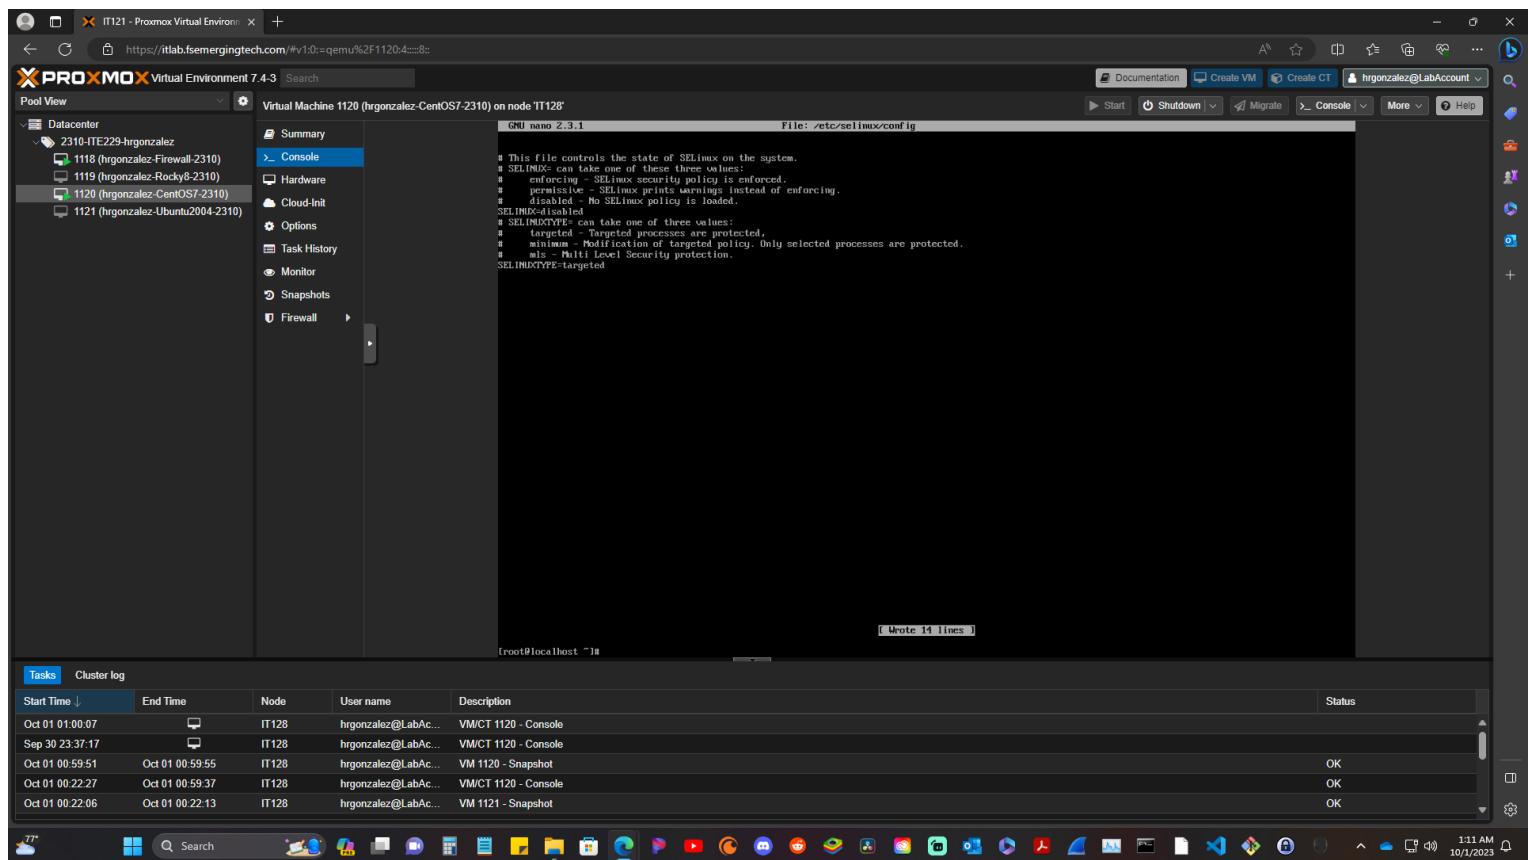

## Test Docker (hello-world)

To make sure Docker is installed properly we need to test it, input command prompt `docker run hello-world`. Docker should respond back with “hello fromm docker!” as pictured below.

## Disable SELinux

Now we need to disable SELinux in order for us to be able to download or get other files that currently we cannot get due to SELinux being enabled. In the terminal window input command prompt `sudo nano /etc/selinux/config` this will take you to the SELinux window where you need to changed enforcing to disabled by hitting the down arrow all the way to the `SELINUX=enforcing` and deleting `enforcing` and typing `disabled`. After hit `control key` and `x` to exit. **Save the changes when prompted**, then hit `enter` on the following prompt. You will be redirected to root name right after.

## Reboot VM

Once back on your root username. Enter command prompt **reboot** to restart CentOS 7.

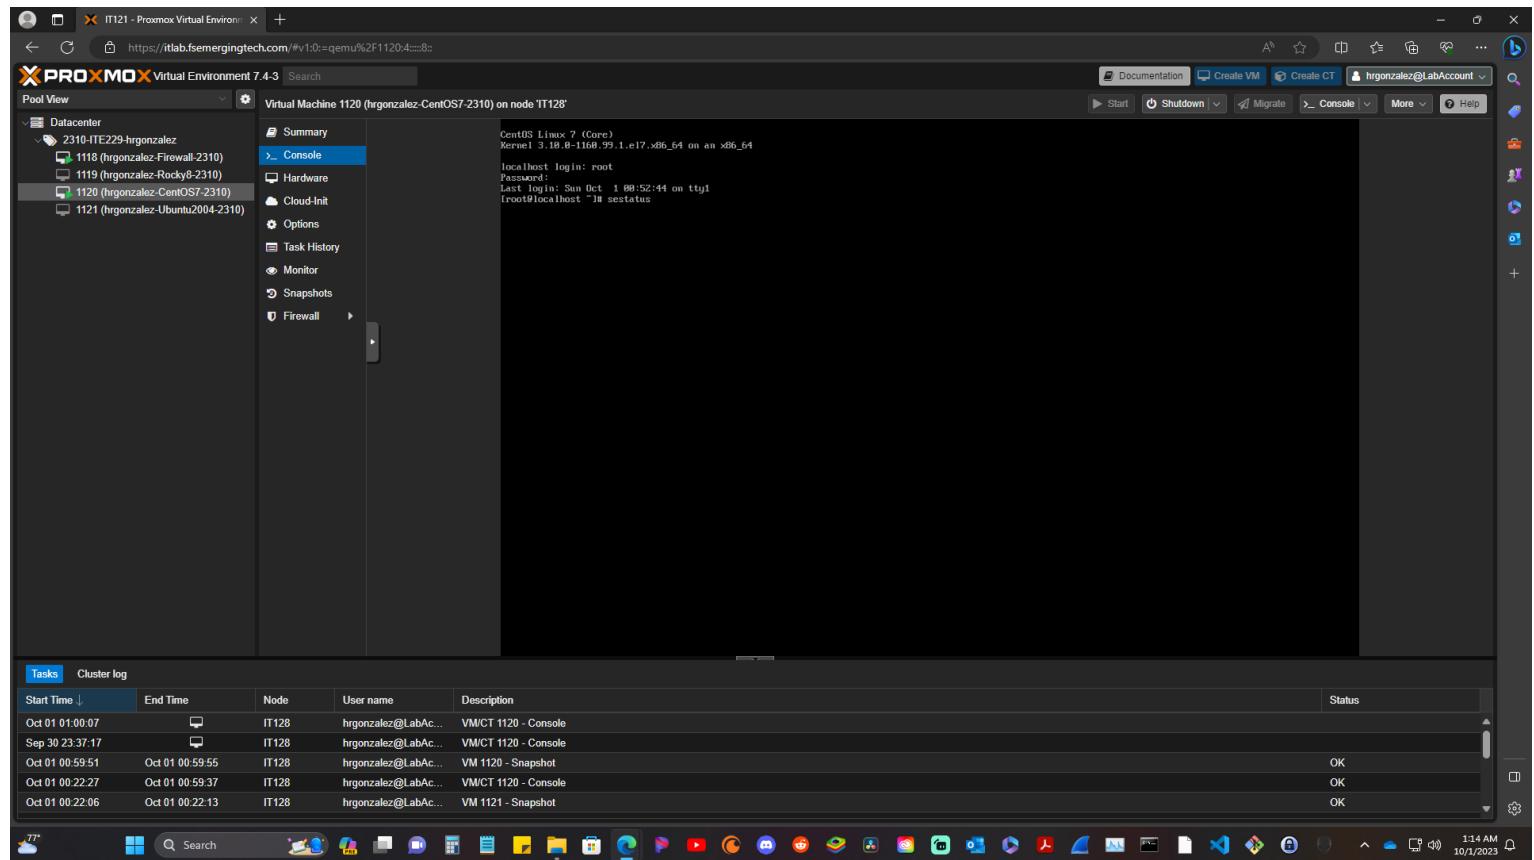

The screenshot shows the Proxmox VE 7.4-3 interface. On the left, the 'Pool View' sidebar lists several virtual machines: 2310-ITE229-hrgonzalez, 1118 (hrgonzalez-Firewall-2310), 1119 (hrgonzalez-Rocky8-2310), 1120 (hrgonzalez-CentOS7-2310) (which is selected), and 1121 (hrgonzalez-Ubuntu2004-2310). The main window displays a terminal session titled 'Virtual Machine 1120 (hrgonzalez-CentOS7-2310) on node IT128'. The terminal shows the SELinux configuration file (`/etc/selinux/config`) with the line `[root@localhost ~]# reboot`. Below the terminal is a 'Cluster log' table with tasks listed:

Start Time	End Time	Node	User name	Description	Status
Oct 01 01:00:07		IT128	hrgonzalez@LabAc...	VM/CT 1120 - Console	
Sep 30 23:37:17		IT128	hrgonzalez@LabAc...	VM/CT 1120 - Console	
Oct 01 00:59:51	Oct 01 00:59:55	IT128	hrgonzalez@LabAc...	VM 1120 - Snapshot	OK
Oct 01 00:22:27	Oct 01 00:59:37	IT128	hrgonzalez@LabAc...	VM/CT 1120 - Console	OK
Oct 01 00:22:06	Oct 01 00:22:13	IT128	hrgonzalez@LabAc...	VM 1121 - Snapshot	OK

The bottom of the screen shows the Windows taskbar with various icons and the date/time: 10/01/2023, 11:3 AM.

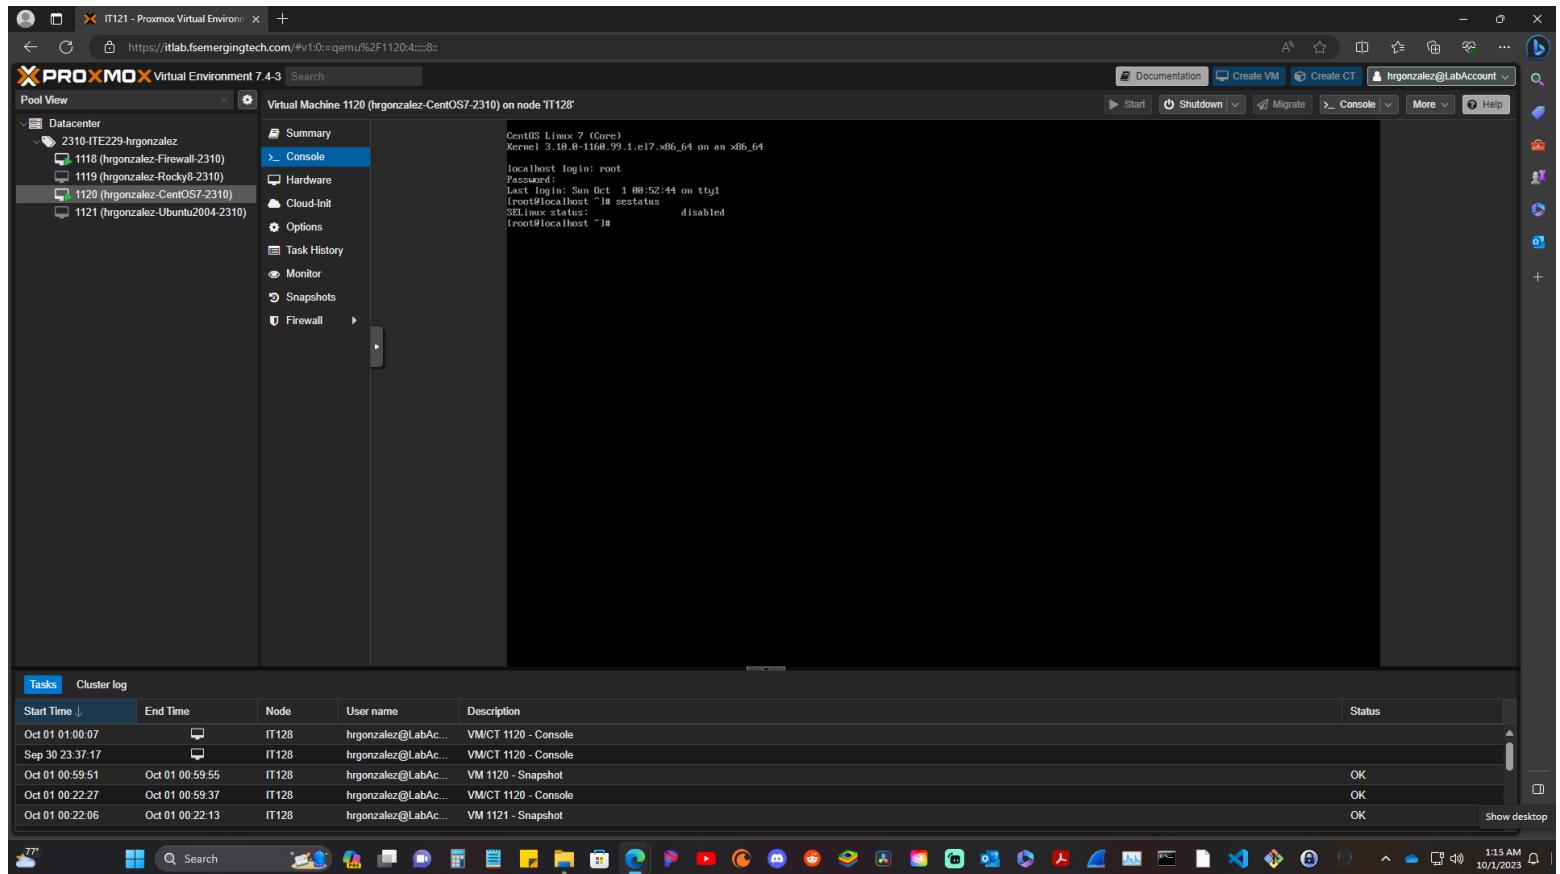

## Test SELinux

Once back on the terminal enter command prompt `sestatus`. \*This step and the one that follows are done at the same time, by inputting the `sestatus` command you are testing and at the same time seeing it's status.

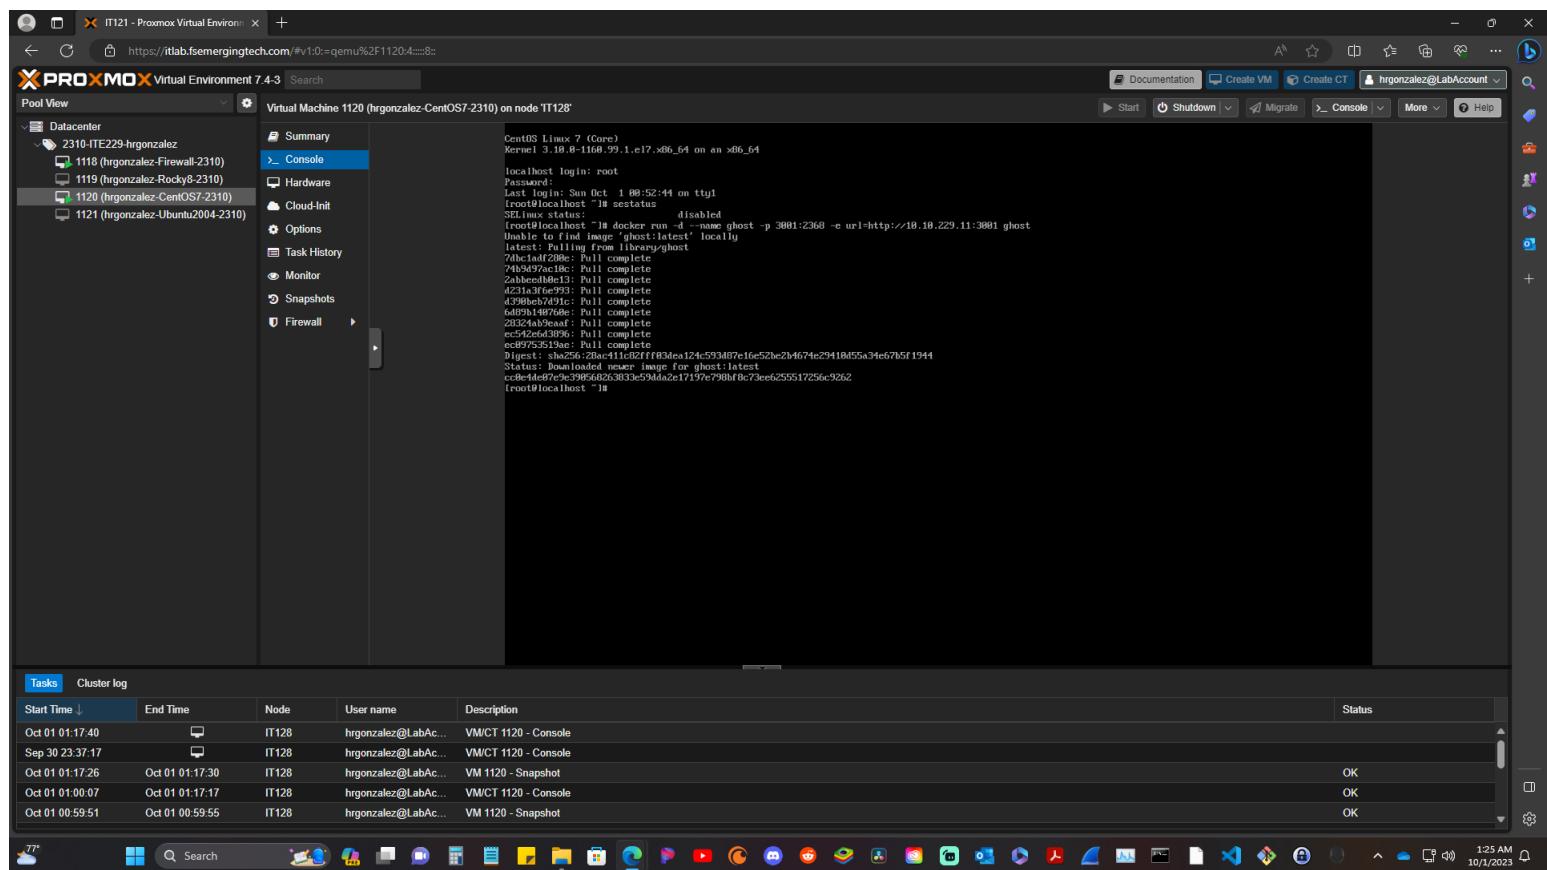

## Confirm SELinux Status

Once rebooted log in with root username and your password. To confirm SELinux is disabled enter command prompt **sestatus** the SELinux status should say **disabled**.

## Install Ghost Docker Container

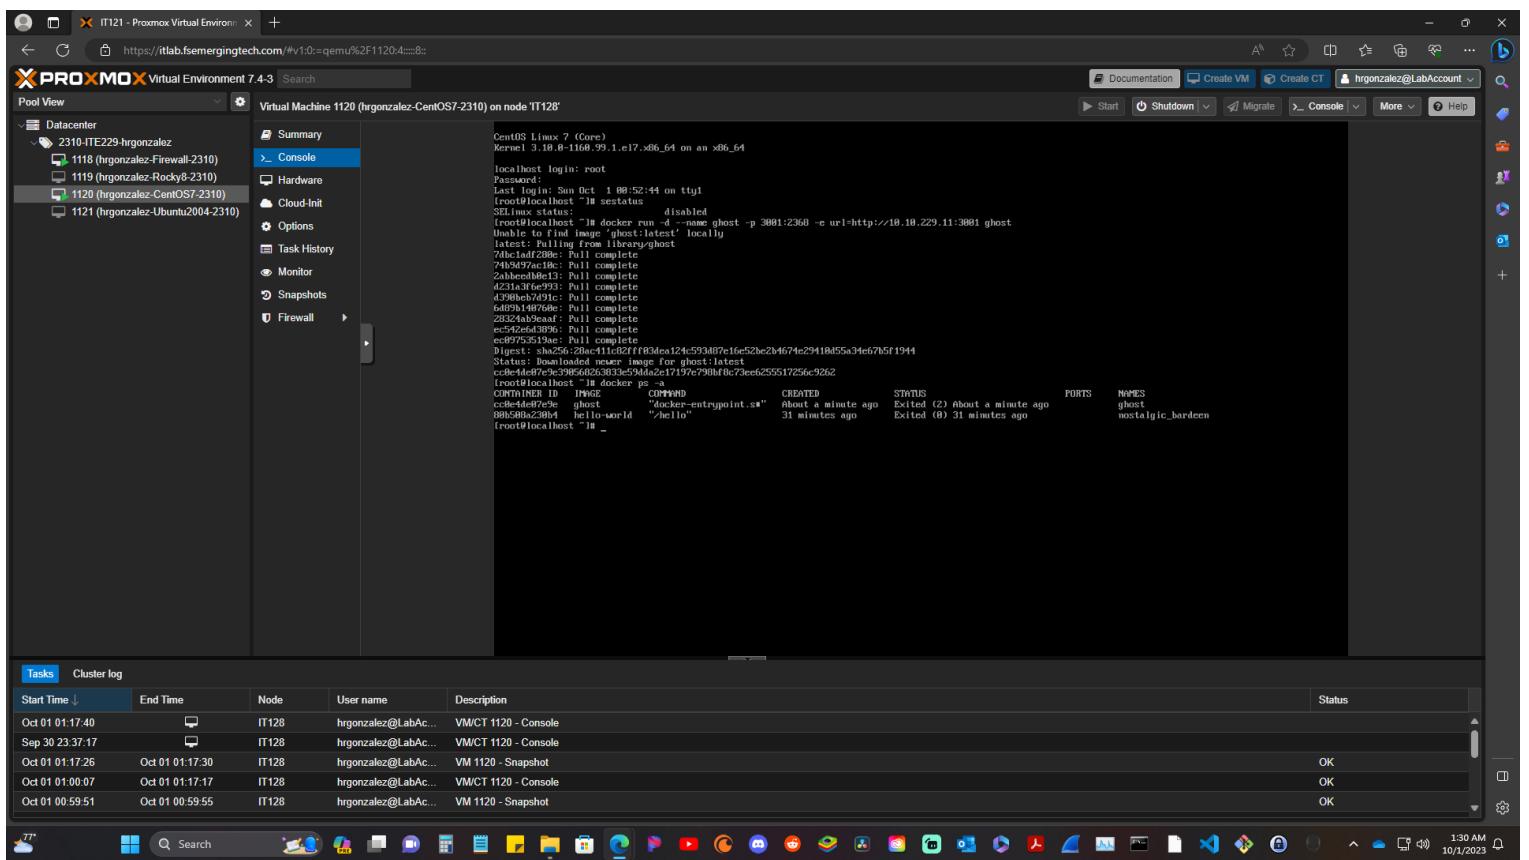

To install Ghost container run command prompt `docker run -d --name ghost -p 3001:2368 -e url=http://10.10.229.11:3001 ghost` if prompted correctly you will see the samething as the picture below.

## Test Ghost

Ghost Container ID

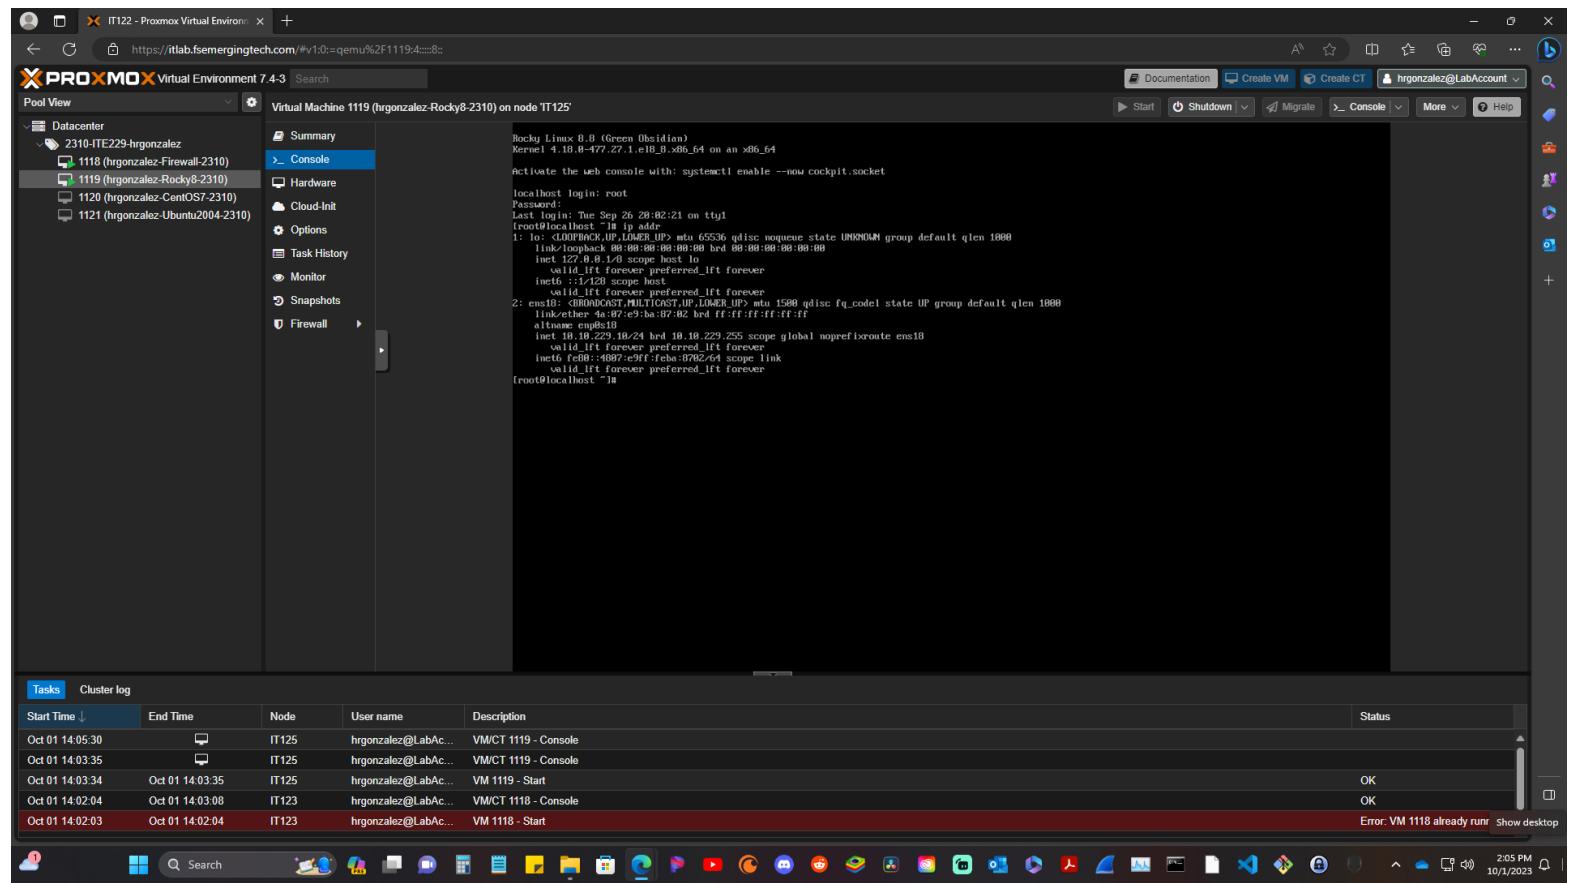

To test Ghost and that it was successfully installed enter command prompt `docker ps -a` this will show the ghost file and It's content including container ID. \*Save the container ID with the file name Ghost, you will need it later.

# NginX Reverse Proxy

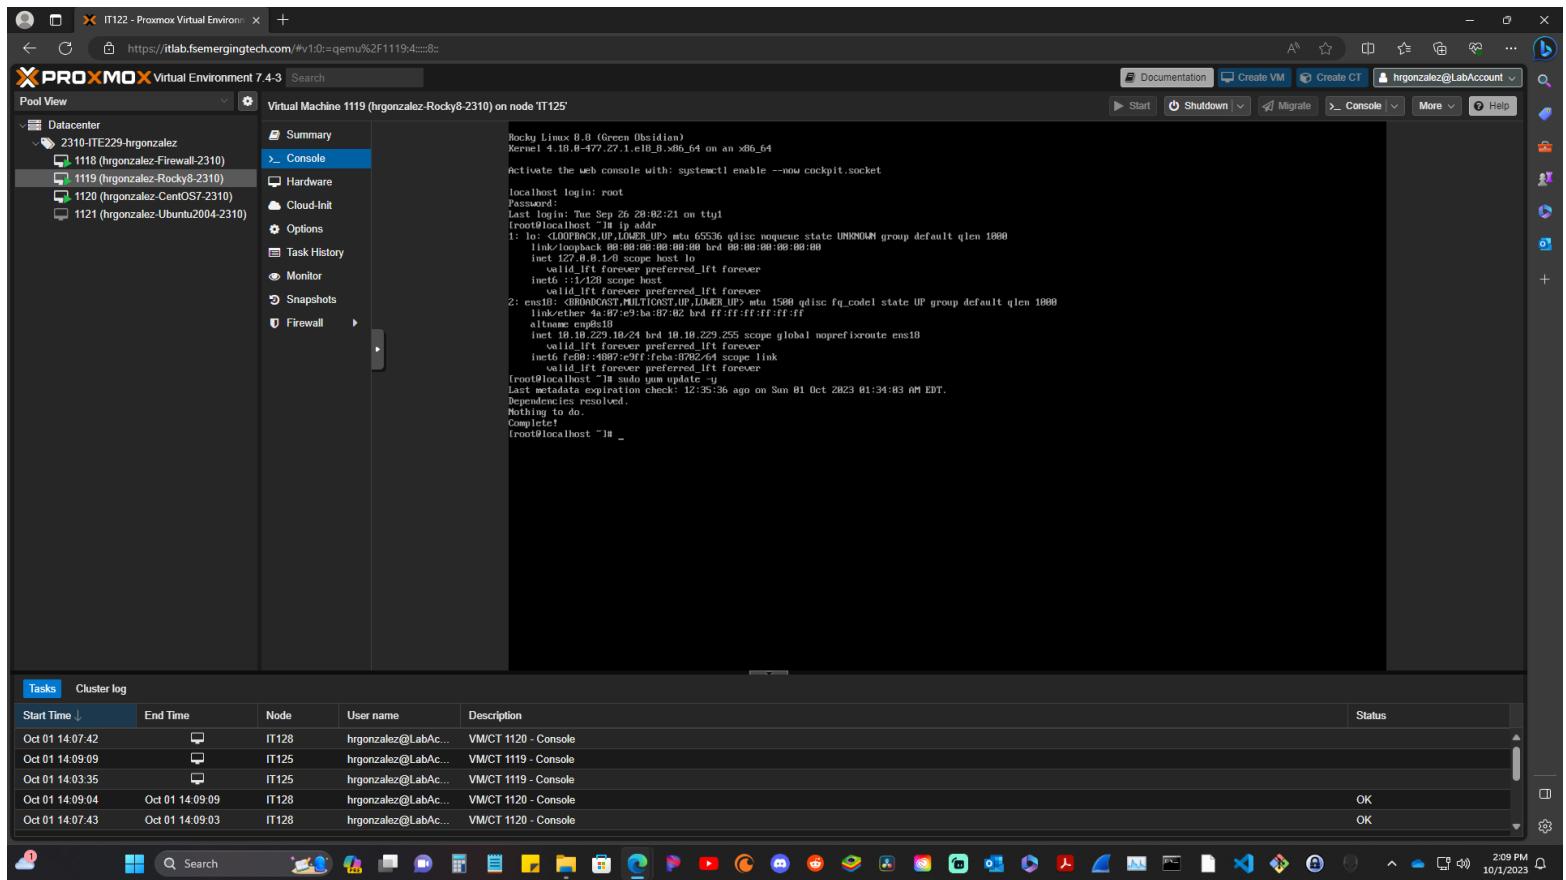

## Show screenshot of your Rocky 8 Console in VE

Open Rocky 8 and log in as root w/password Fullsail1!. In the terminal window verify IP Address by entering command prompt `ip addr` and make sure the ip address is 10.10.229.10/24

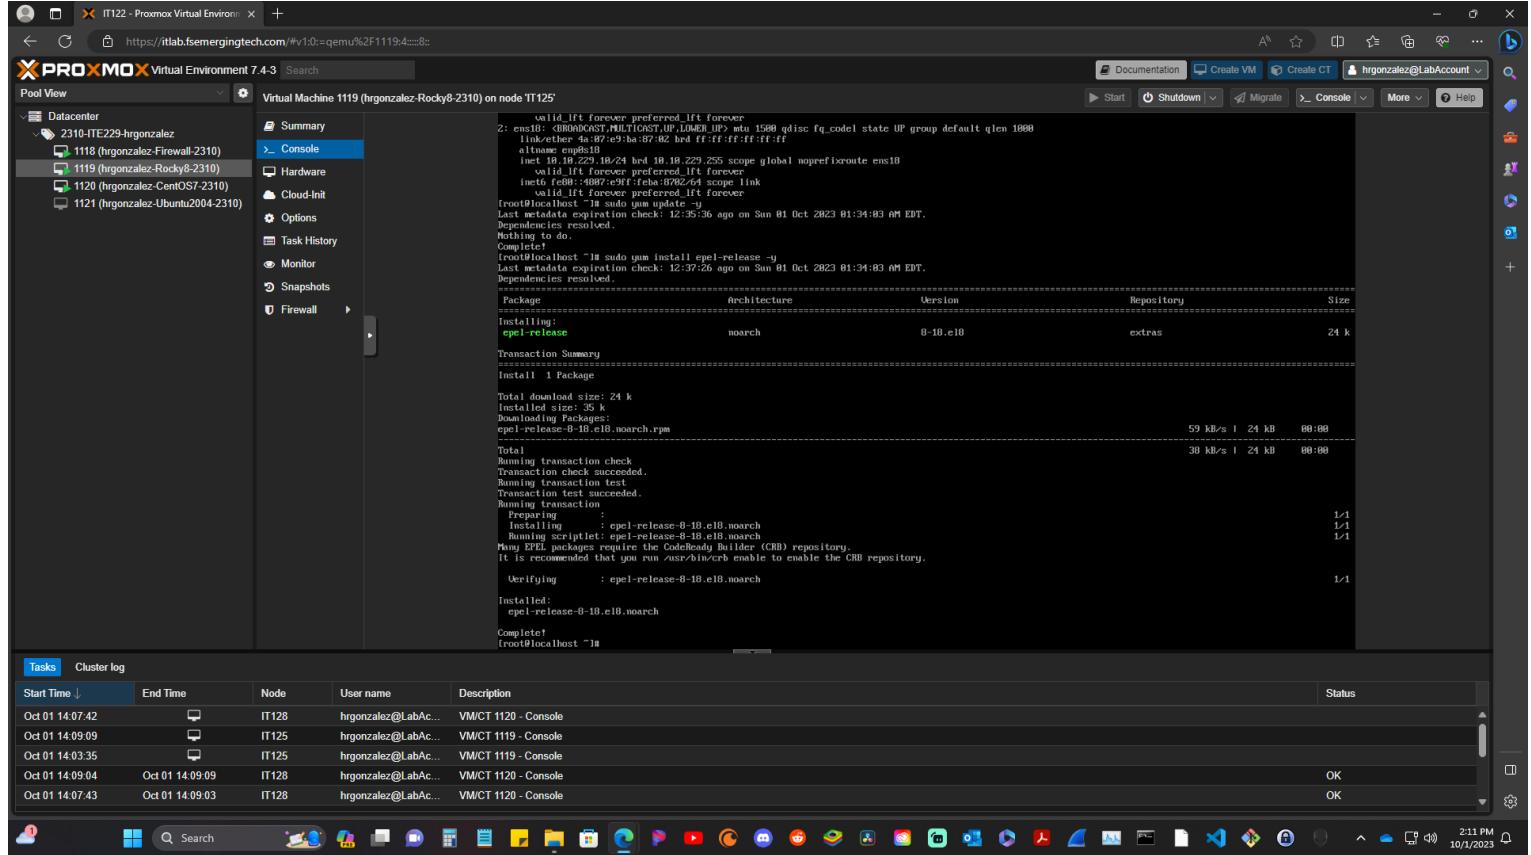

## Update Rocky 8

Next make sure you are using all the current updates and files by entering the command prompt **sudo yum update -y**

## Install EPEL Packages

Install all the extra packages for enterprise Linux (EPEL) by inputting the command prompt **sudo yum install epel-release -y**

## Disable SELinux

Now we need to disable SELinux in order for us to be able to download or get other files that currently we cannot get due to SELinux being enabled. In the terminal window input command prompt `sudo nano /etc/selinux/config` this will take you to the SELinux window where you need to changed enforcing to disabled by hitting the down arrow all the way to the `SELINUX=enforcing` and deleting `enforcing` and typing `disabled`. After hit `control key` and `x` to exit. **Save the changes when prompted**, then hit `enter` on the following prompt. You will be redirected to root name right after.

## Reboot VM

Once back on your root username. Enter command prompt **reboot** to restart Rocky 8.

The screenshot shows the Proxmox Virtual Environment 7.4-3 interface. On the left, the 'Pool View' sidebar lists several virtual machines: 2310-ITE229-hrgonzalez, 1118 (hrgonzalez-Firewall-2310), 1119 (hrgonzalez-Rocky8-2310), 1120 (hrgonzalez-CentOS7-2310), and 1121 (hrgonzalez-Ubuntu2004-2310). The 'Console' tab is selected for VM 1119. The main window displays a terminal session with the following commands and output:

```
[root@localhost ~]# systemctl stop firewalld
[root@localhost ~]# systemctl disable firewalld
Removed '/etc/systemd/system/multi-user.target.wants/firewalld.service'.
Removed '/etc/systemd/system/dbus-org.fedoraproject.FirewallD1.service'.
[root@localhost ~]# reboot
```

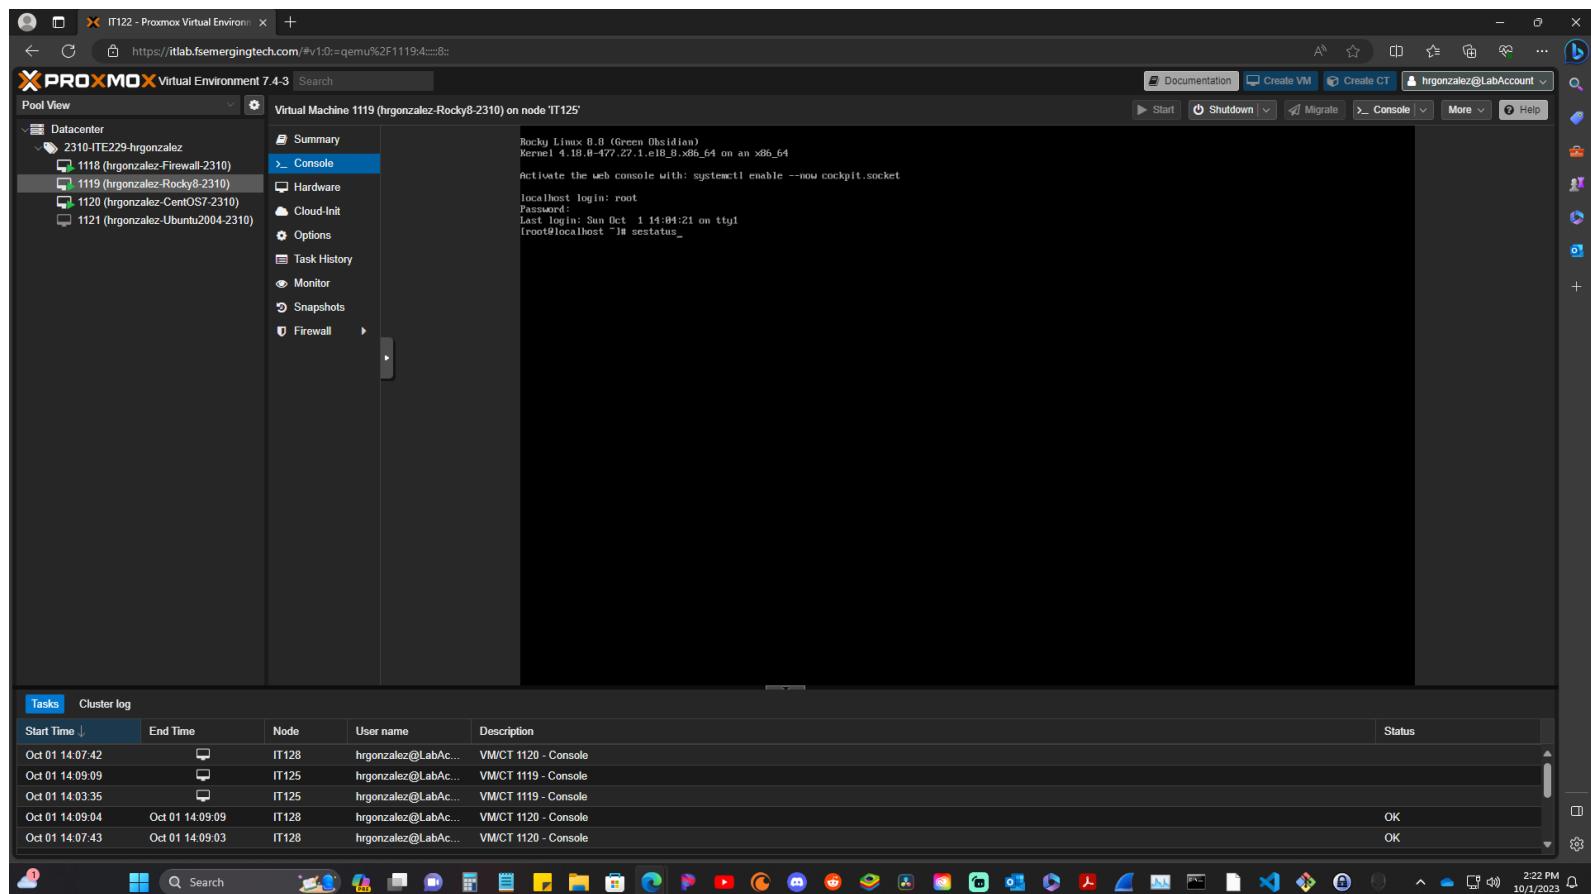

Below the terminal, the 'Tasks' and 'Cluster log' sections show recent activity:

Start Time	End Time	Node	User name	Description	Status
Oct 01 14:07:42		IT128	hrgonzalez@LabAc...	VM/CT 1120 - Console	
Oct 01 14:09:09		IT125	hrgonzalez@LabAc...	VM/CT 1119 - Console	
Oct 01 14:09:35		IT125	hrgonzalez@LabAc...	VM/CT 1119 - Console	
Oct 01 14:09:04	Oct 01 14:09:09	IT128	hrgonzalez@LabAc...	VM/CT 1120 - Console	OK
Oct 01 14:07:43	Oct 01 14:09:03	IT128	hrgonzalez@LabAc...	VM/CT 1120 - Console	OK

The bottom of the screen shows the Windows taskbar with various pinned icons.

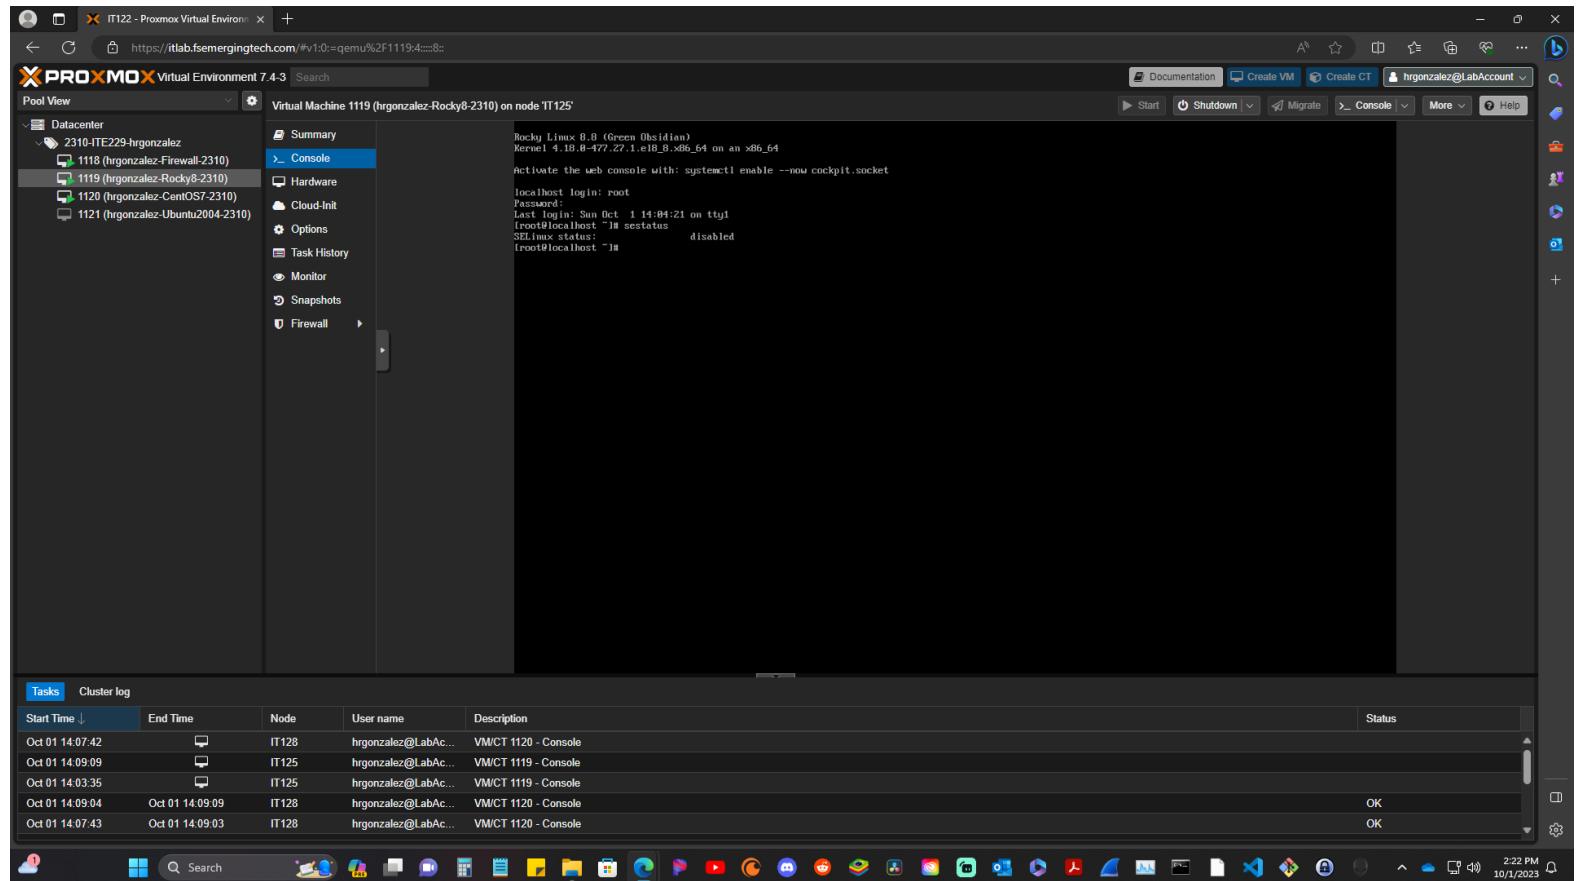

## Test SELinux

Once back on the terminal enter command prompt `sestatus`. \*This step and the one that follows are done at the same time, by inputting the `sestatus` command you are testing and at the same time seeing it's status.

## Confirm SELinux Status

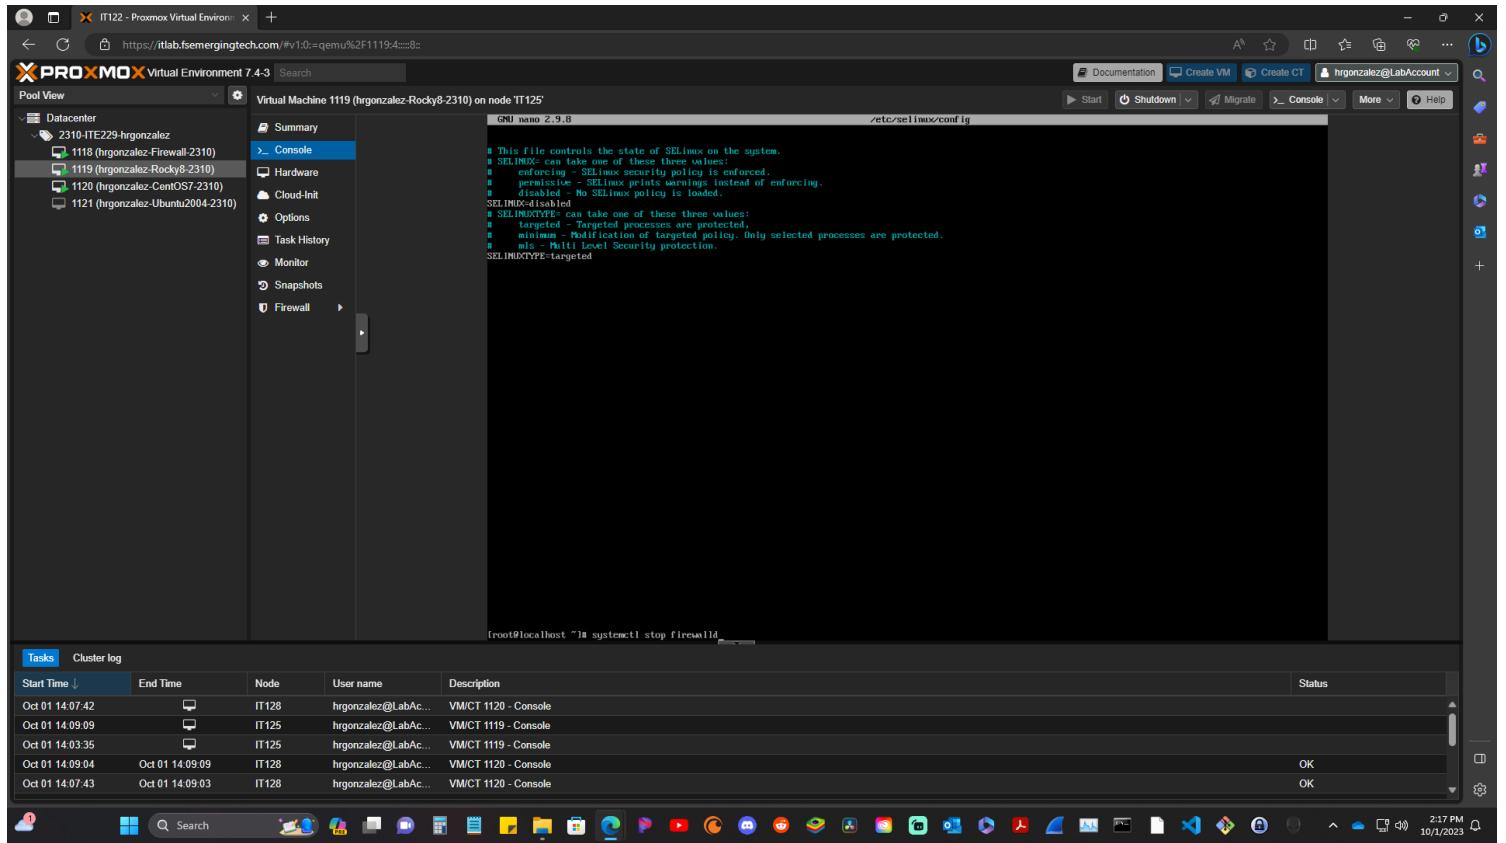

By inputting command prompt **sestatus** you are able to see if selinux is disabled.

## Rocky Firewall

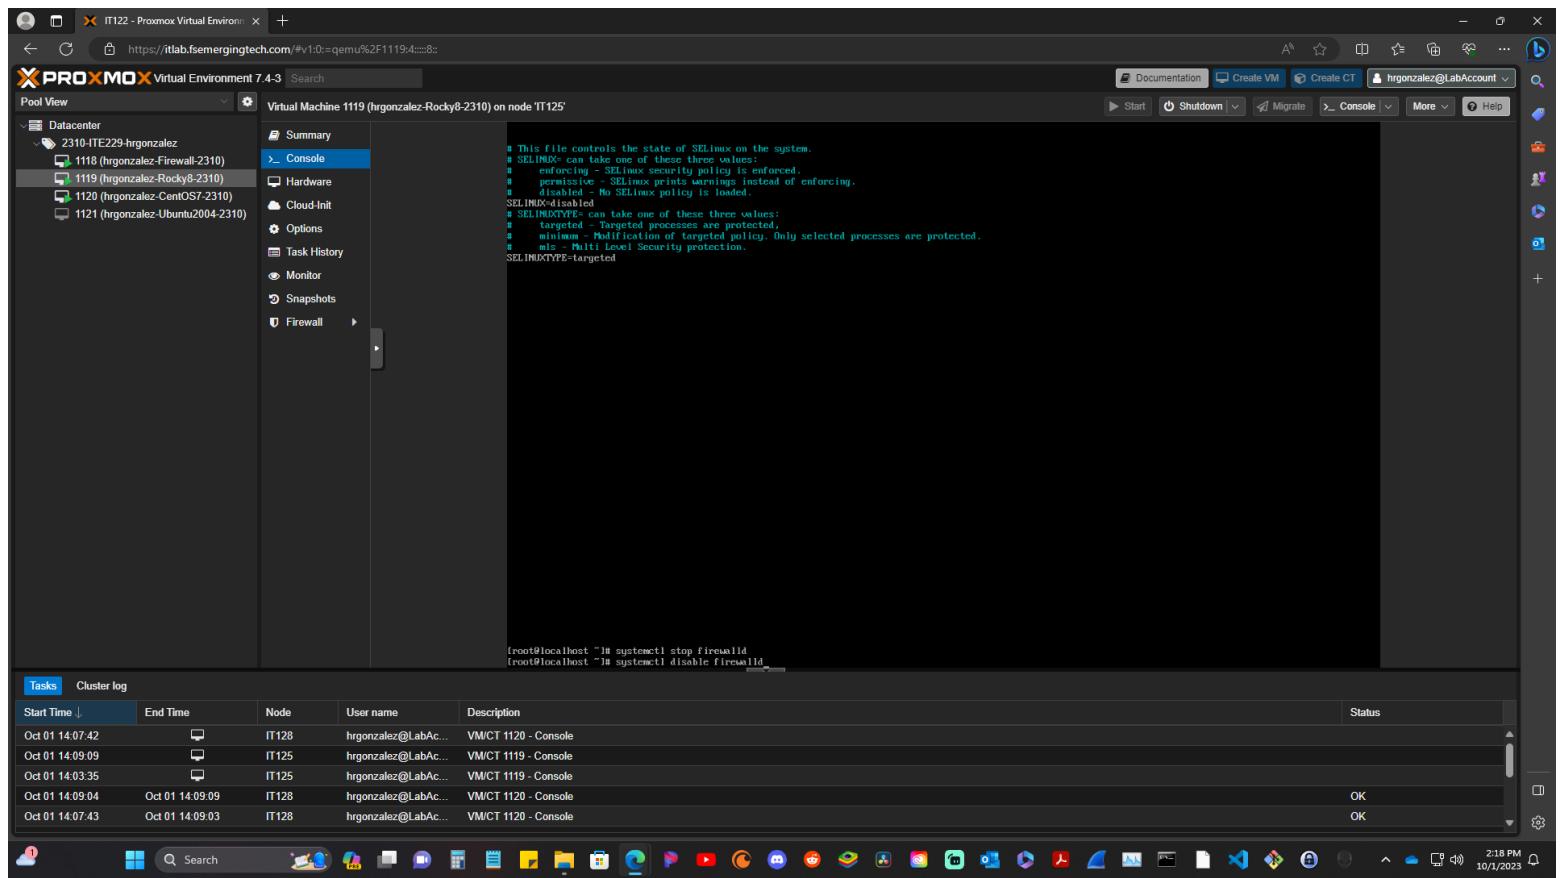

### Stop Firewall

To stop firewall enter command prompt **systemctl stop firewalld** and hit enter. This will stop the firewall.

## Disable Firewall

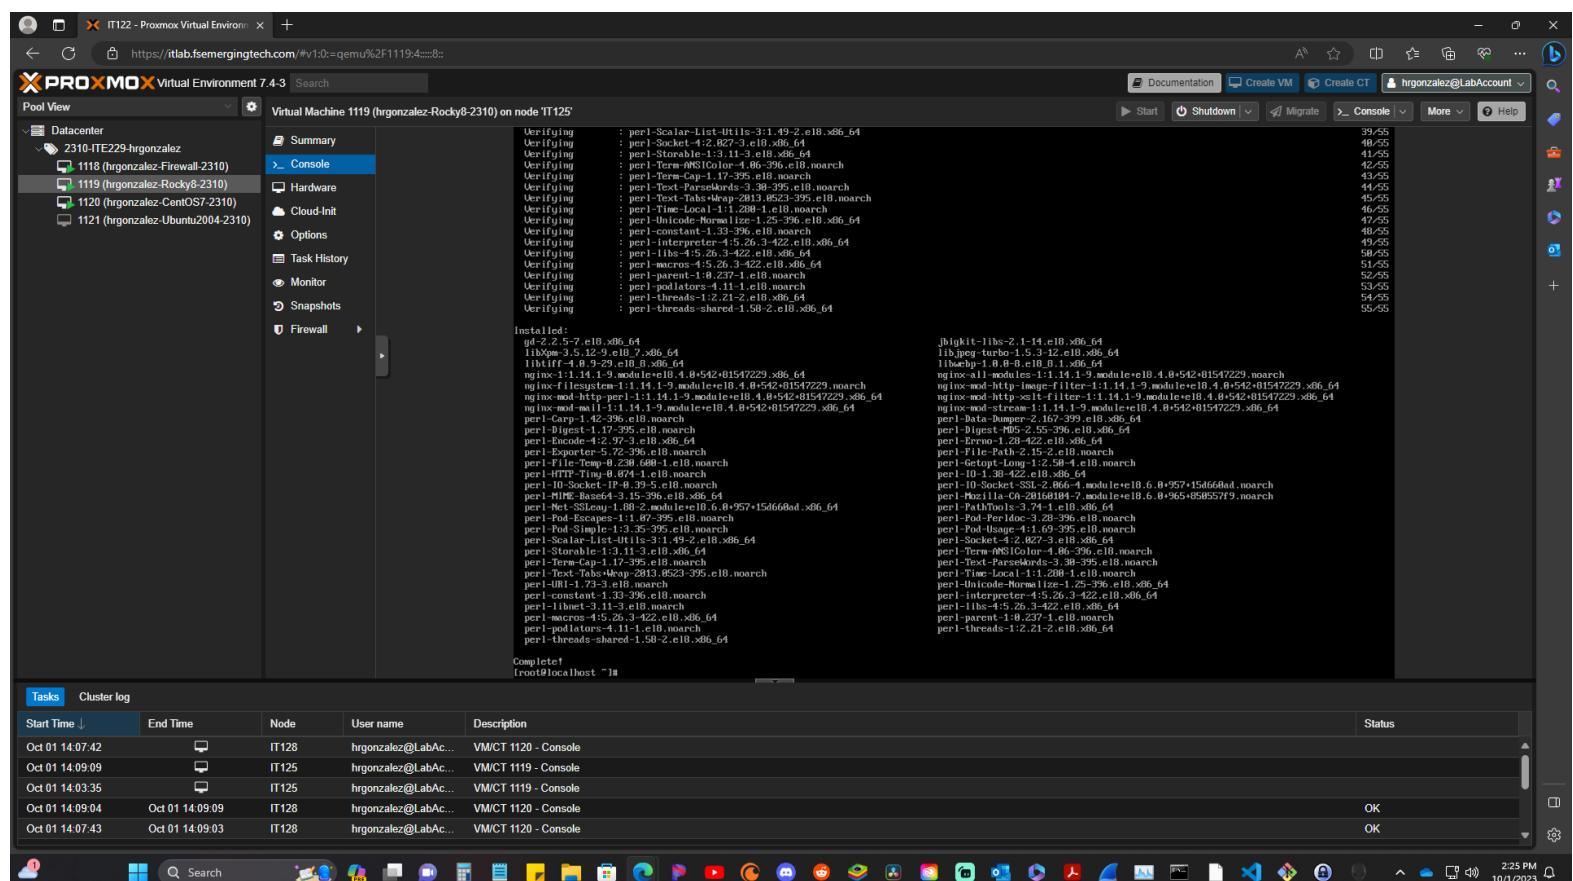

After enter command prompt `systemctl disable firewalld` and hit enter. This will disable the firewall.

## NginX

### Install NginX

Next, we will be installing Nginx. In order to do so, we need to grab it from its location. Enter command prompt `sudo yum install nginx -y`. Let it run its installation process, and after it finishes installing you should see a complete window like the one below.

The screenshot shows a terminal window within a Proxmox Virtual Environment interface. The title bar indicates it's running on node IT125. The terminal output displays the results of a yum install command for nginx:

2.26 PM 10/1/2023

## Enable NginX

Now we need to enable Nginx. In order to do this input command prompt `systemctl enable nginx` then hit enter. It should [create a symlink](#) and if everything is good to this point your terminal should look like the picture below.

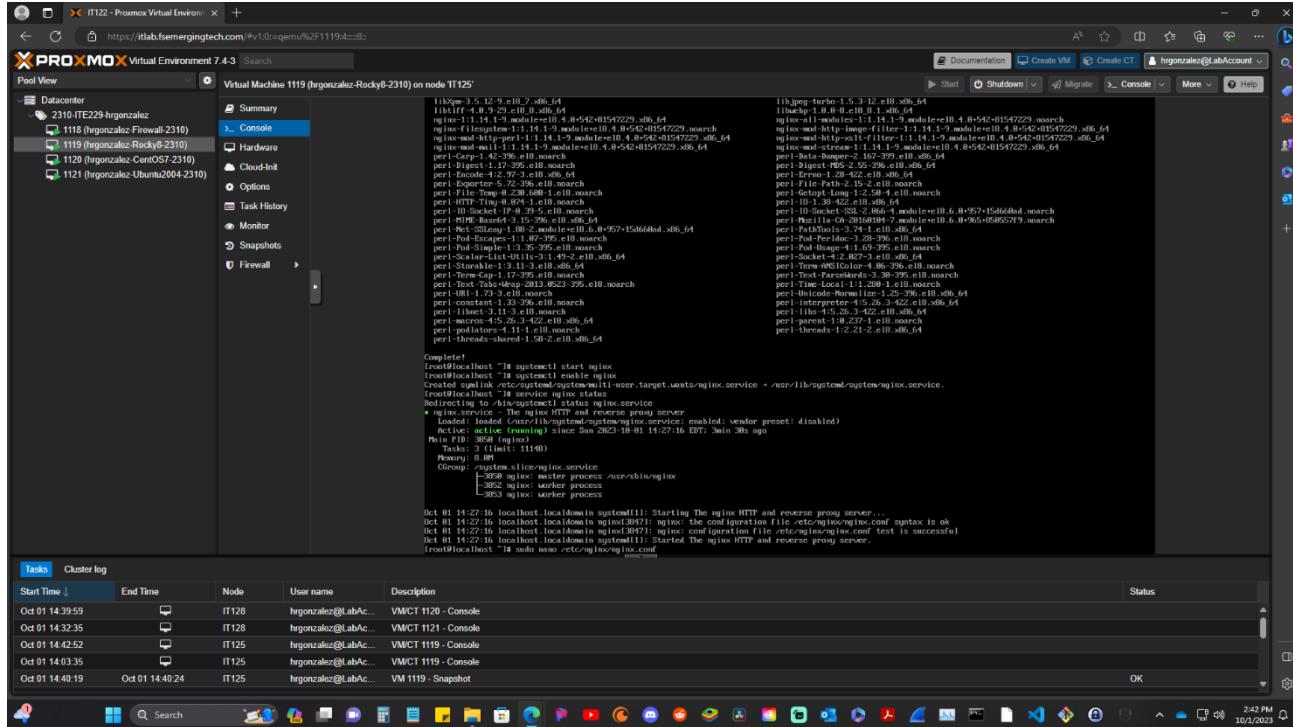

## Test NginX

Time to test Nginx, by inputting command prompt `service nginx status` you should see that nginx is actively running.

## Reverse Proxy for Ghost Site

### Edit NginX configuration file

This part involves a couple of steps. Input command prompt `sudo nano /etc/nginx/nginx.conf` this will take you to the nginx configuration file. In this file we are going to add some changes.

Once inside the configuration file you want to scroll down using the arrow key until you hit the section (\*Don't pay attention to the text in between both green lines, this is what we are going to be adding\*) that say # Load configuration in turquoise color and under the turquoise color it should say include /etc/nginx follow by location underneath. Use picture as reference. Once in this location you are going to type in the following code. Use the picture as reference because everything needs to be exactly the same.

```
location /blog {
    proxy_pass http://10.10.229.11:3001;
    proxy_set_header Host $http_host;      # required
    proxy_set_header X-Real-IP $remote_addr; # pass on
    proxy_set_header X-Forwarded-For $proxy_add_x_forwarded_for;
    proxy_read_timeout 900;
}
```

```
sendfile          on;
tcp_nopush        on;
tcp_nodelay       on;
keepalive_timeout 65;
types_hash_max_size 2048;

include           /etc/nginx/mime.types;
default_type      application/octet-stream;

# Load modular configuration files from the /etc/nginx/conf.d directory.
# See http://nginx.org/en/docs/ngx_core_module.html#include
# for more information.
include /etc/nginx/conf.d/*.conf;

server {
    listen      80 default_server;
    listen      [::]:80 default_server;
    server_name _;
    root        /usr/share/nginx/html;

    # Load configuration files for the default server block.
    include /etc/nginx/default.d/*.conf;

    location / {
    }

    location /blog {
        proxy_pass          http://10.10.229.11:3001;
        proxy_set_header    Host $http_host;      # required for docker client's sake
        proxy_set_header    X-Real-IP $remote_addr; # pass on real client's IP
        proxy_set_header    X-Forwarded-For $proxy_add_x_forwarded_for;
        proxy_read_timeout 900;
    }
}

error_page 404 /404.html;
    location = /40x.html {
}

error_page 500 502 503 504 /50x.html;
    location = /50x.html {
}
```

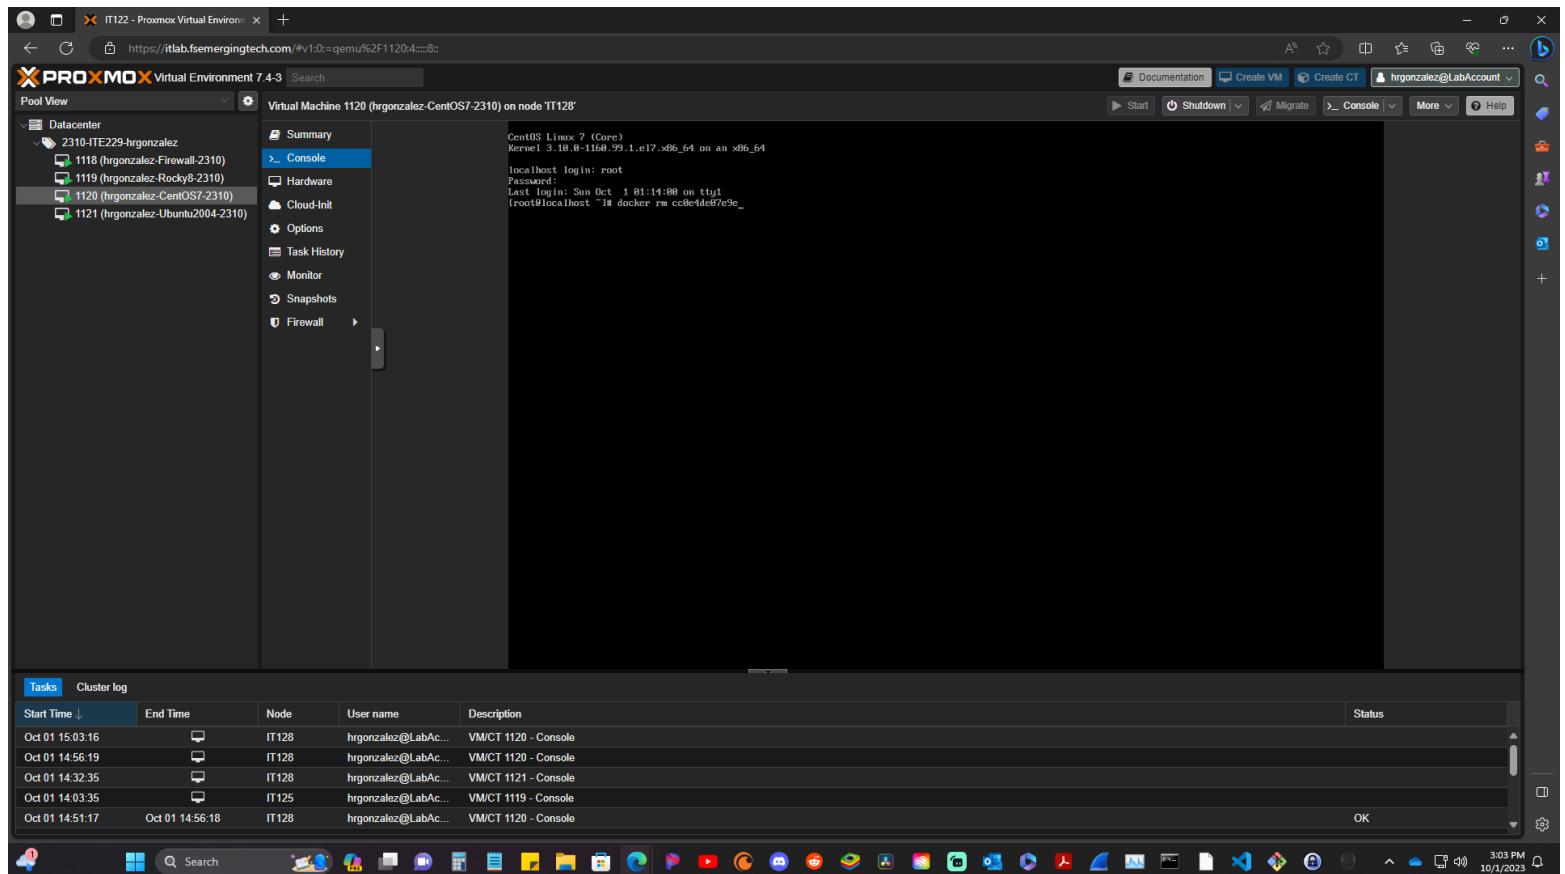

## Reload NginX service

Once you finish typing everything as instructed hit **control key** and **E** to exit, **it will prompt if you want to save changes make sure you hit Y for yes then hit enter**. Once you hit enter it will take you back to the root user just like in the picture below saving all the changes you just made.

## Terminate Docker

Now we need to terminate Docker. Input command prompt `docker rm _____` in the blank you need to type in the **container id** you saved/wrote down from previous steps.

## Delete Ghost Container

Once you input the command prompt from above and hit enter you will see the id will appear again and then redirect you to root username. This means it was successfully deleted.

The screenshot shows the Proxmox Virtual Environment 7.4-3 interface. On the left, the Datacenter tree view lists several virtual machines: 2310-ITE229-hrgonzalez, 1118 (hrgonzalez-Firewall-2310), 1119 (hrgonzalez-Rocky8-2310), 1120 (hrgonzalez-CentOS7-2310) which is selected, and 1121 (hrgonzalez-Ubuntu2004-2310). The main pane displays the console of VM 1120. The terminal output shows:

```
CentOS Linux 7 (Core)
Kernel 3.10.0-1160.99.1.el7.x86_64 on an x86_64
localhost login: root
Password:
Last login: Sun Oct 1 11:14:09 on ttys0
root@localhost ~]# docker rm ccb844d87c9e
ccb844d87c9e
[root@localhost ~]#
```

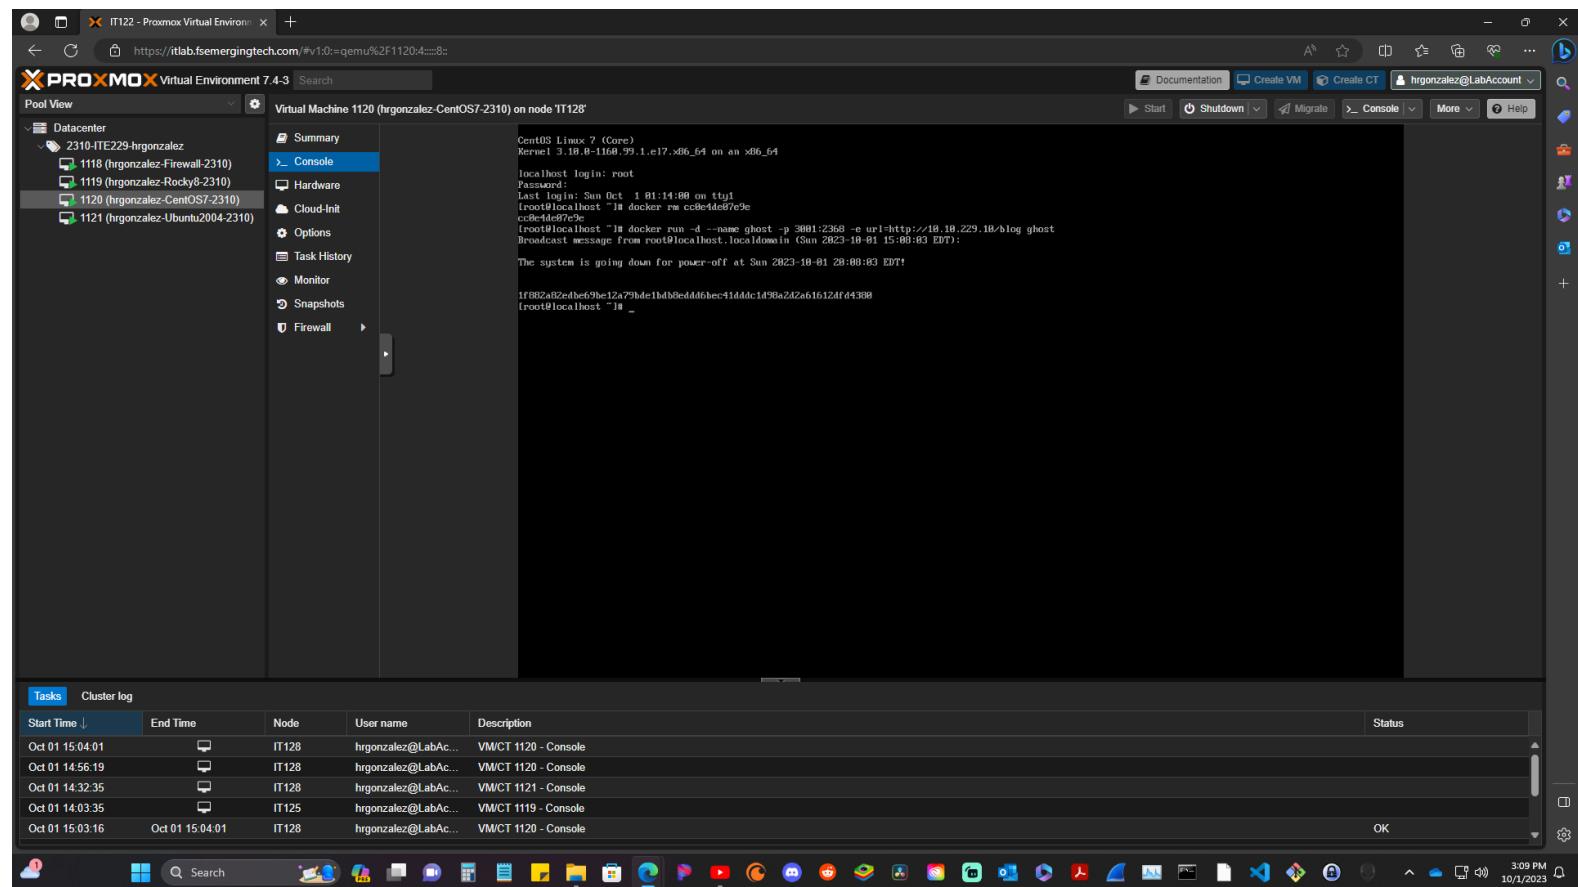

Below the terminal, a table titled "Tasks" shows recent activities:

Start Time	End Time	Node	User name	Description	Status
Oct 01 15:04:01		IT128	hrgonzalez@LabAc...	VMCT 1120 - Console	
Oct 01 14:56:19		IT128	hrgonzalez@LabAc...	VMCT 1120 - Console	
Oct 01 14:32:35		IT128	hrgonzalez@LabAc...	VMCT 1121 - Console	
Oct 01 14:03:35		IT125	hrgonzalez@LabAc...	VMCT 1119 - Console	
Oct 01 15:03:16	Oct 01 15:04:01	IT128	hrgonzalez@LabAc...	VM/CT 1120 - Console	OK

The system tray at the bottom shows various icons, and the status bar indicates "3:04 PM 10/1/2023".

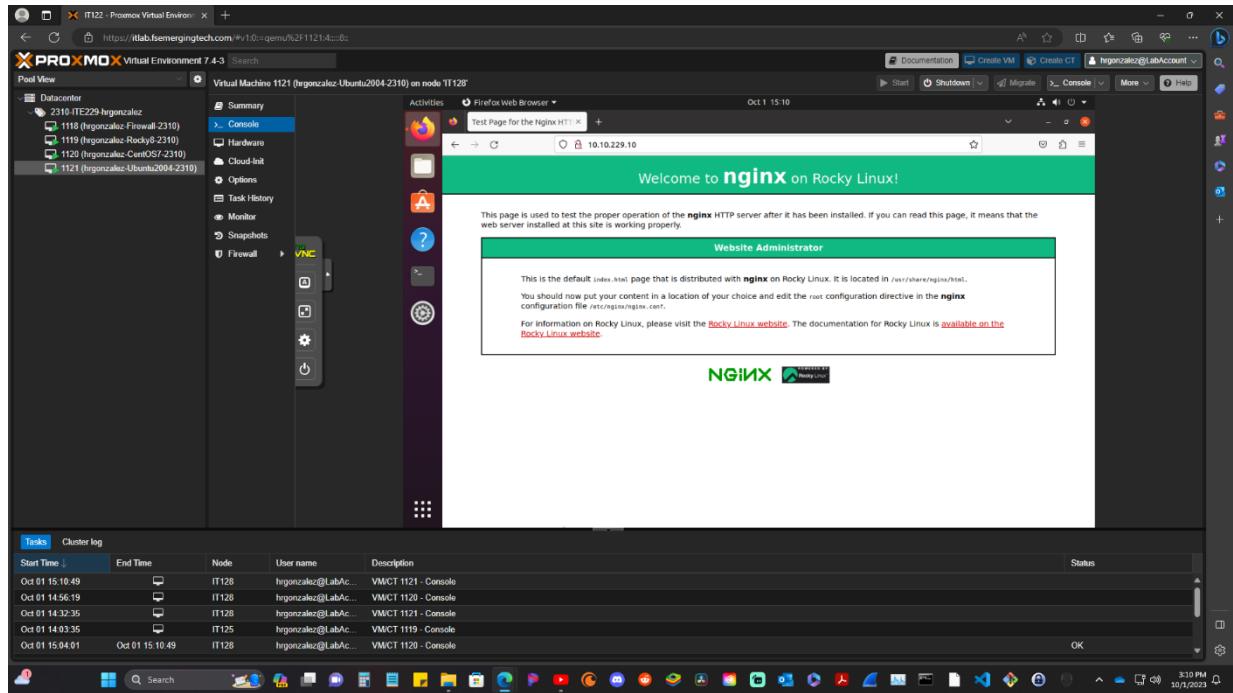

## Create New Ghost Container

Now we need to create a new ghost container and in order to do this you need to type command prompt `docker run -d --name ghost -p 3001:2368 -e url=http://10.10.229.10/blog ghost`. This will create a new ghost container id. If successful it should give you a long name with letters and numbers before returning you back to your root username.

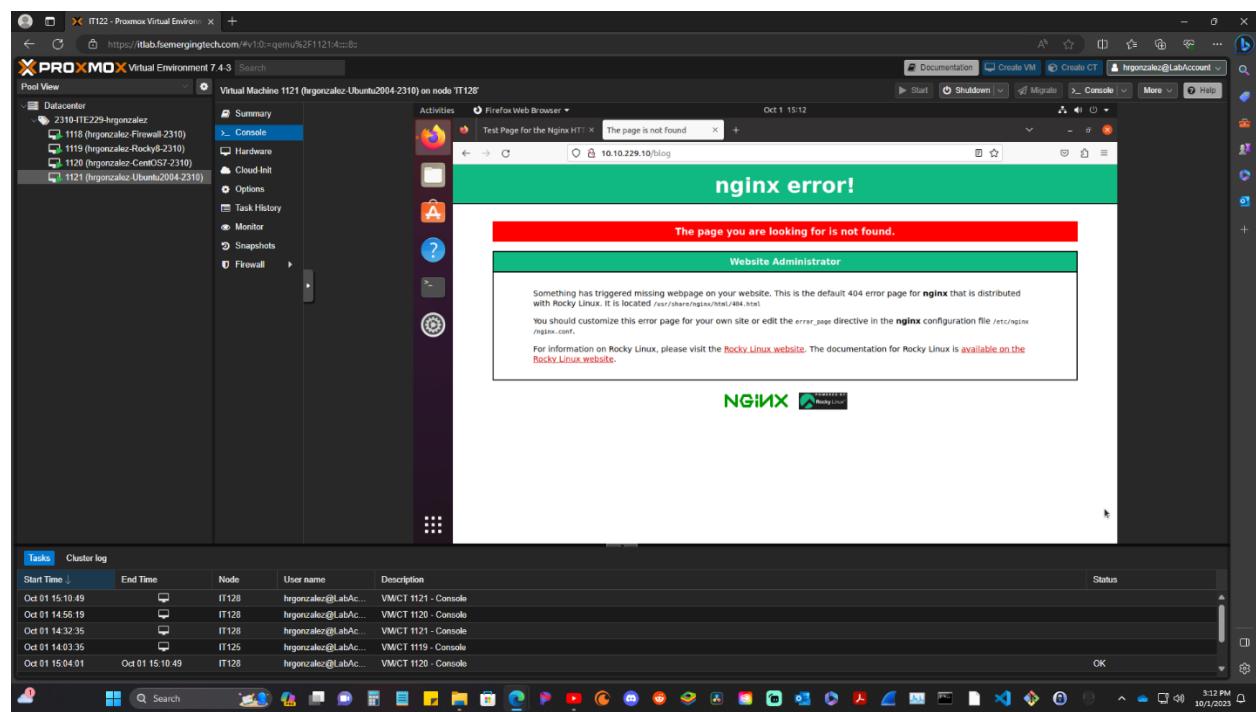

## Browse to Ghost

Now we need to verify everything is working properly with Nginx and the blog ip address. [Log in to your Ubuntu VM](#) using the credentials **user** and **Fullsail1!** for the password. Once in Ubuntu VM go to [firefox web browser](#) and type <http://10.10.229.10>. in the url. You should get a window that looks like the one below.

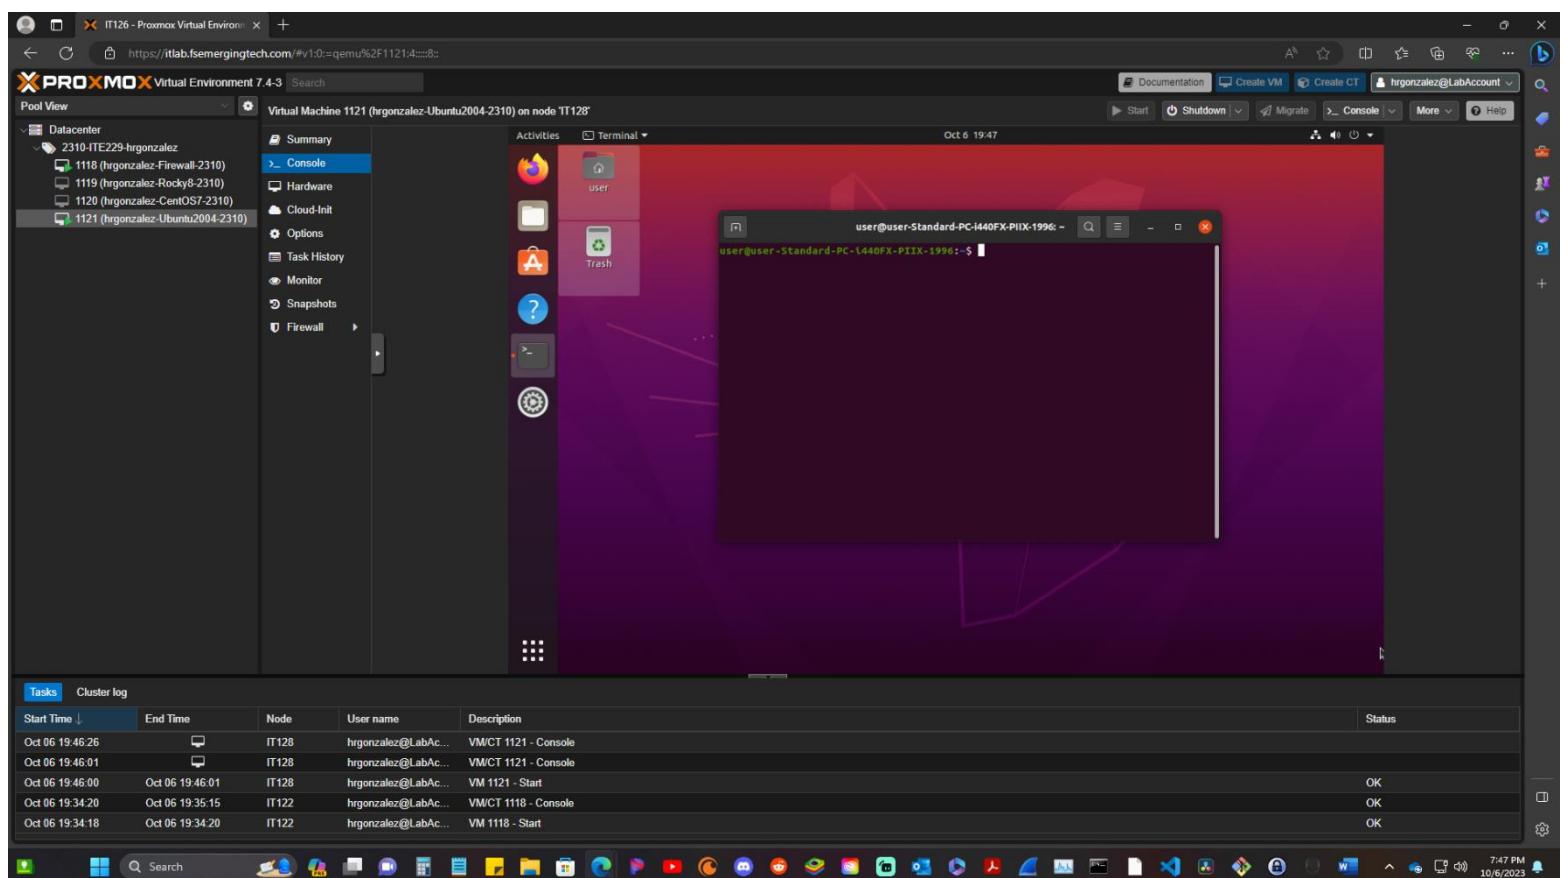

Now [open a new window in firefox](#) and type in <http://10.10.229.10/blog> in the url. You should get a window like the one below. Don't worry about the error, because we are still not finished setting up Word press, we are only verifying Nginx.

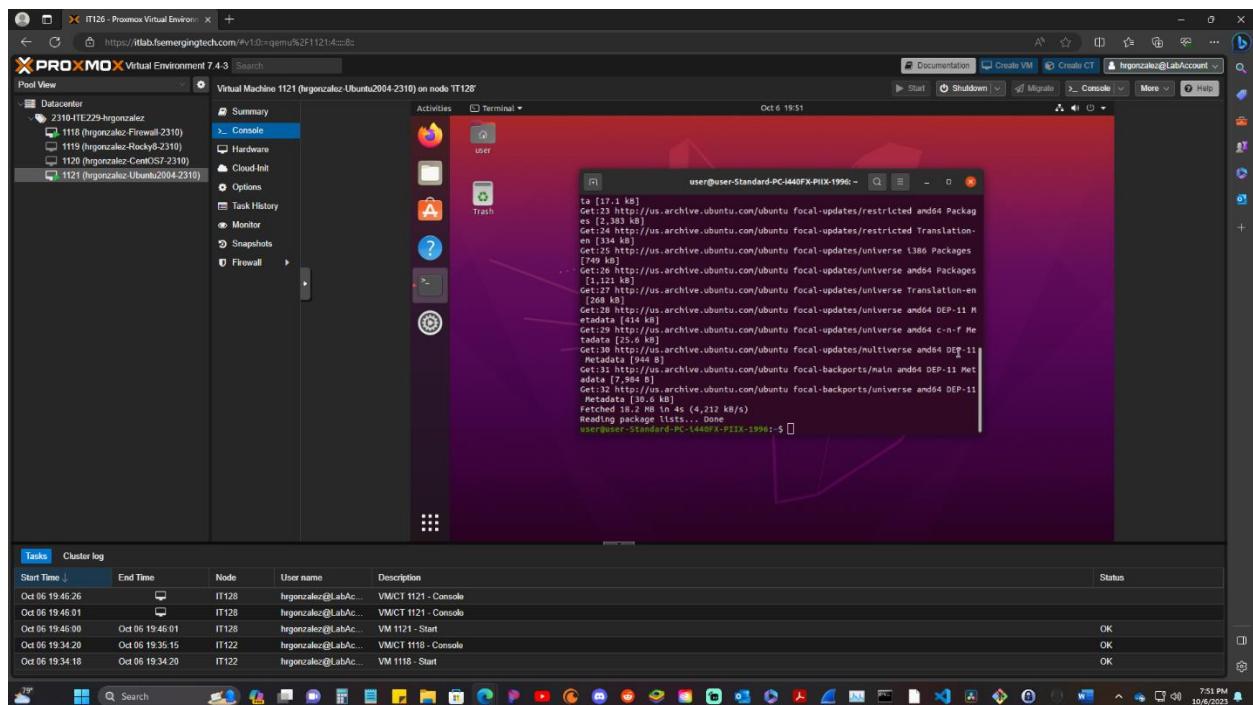

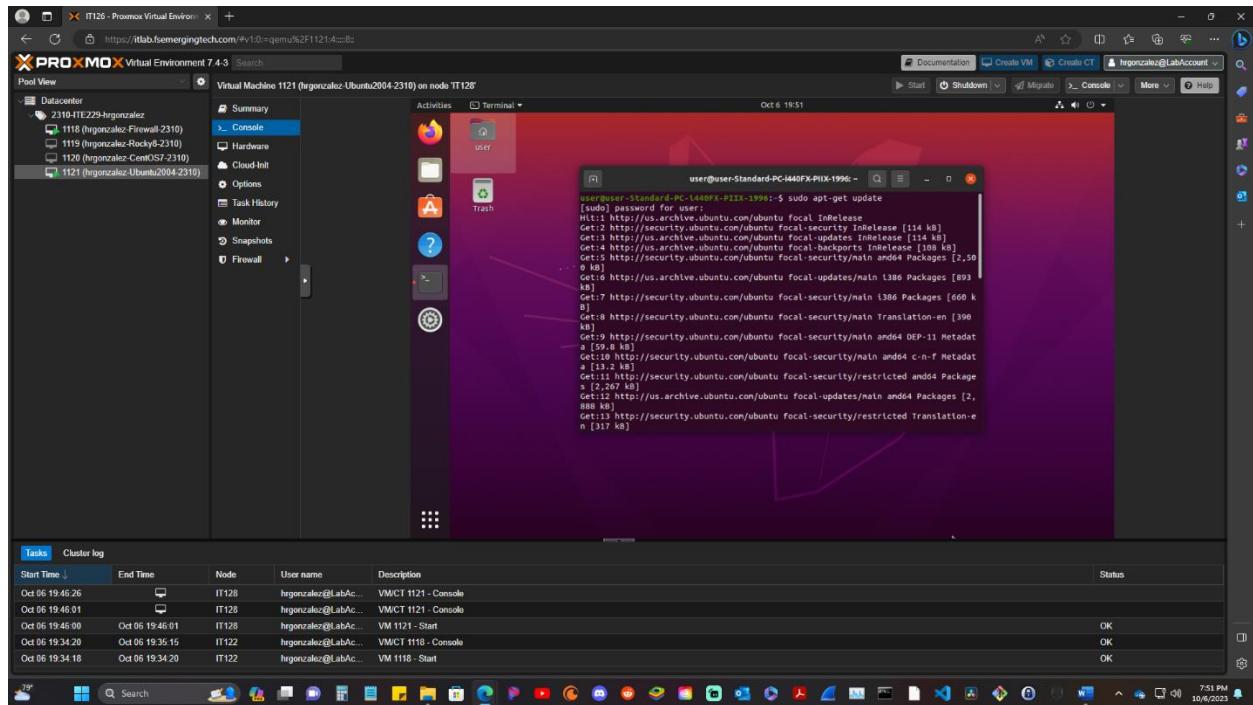

# WordPress on Ubuntu - LAMP Stack

Show screenshot of your Ubuntu Console in VE

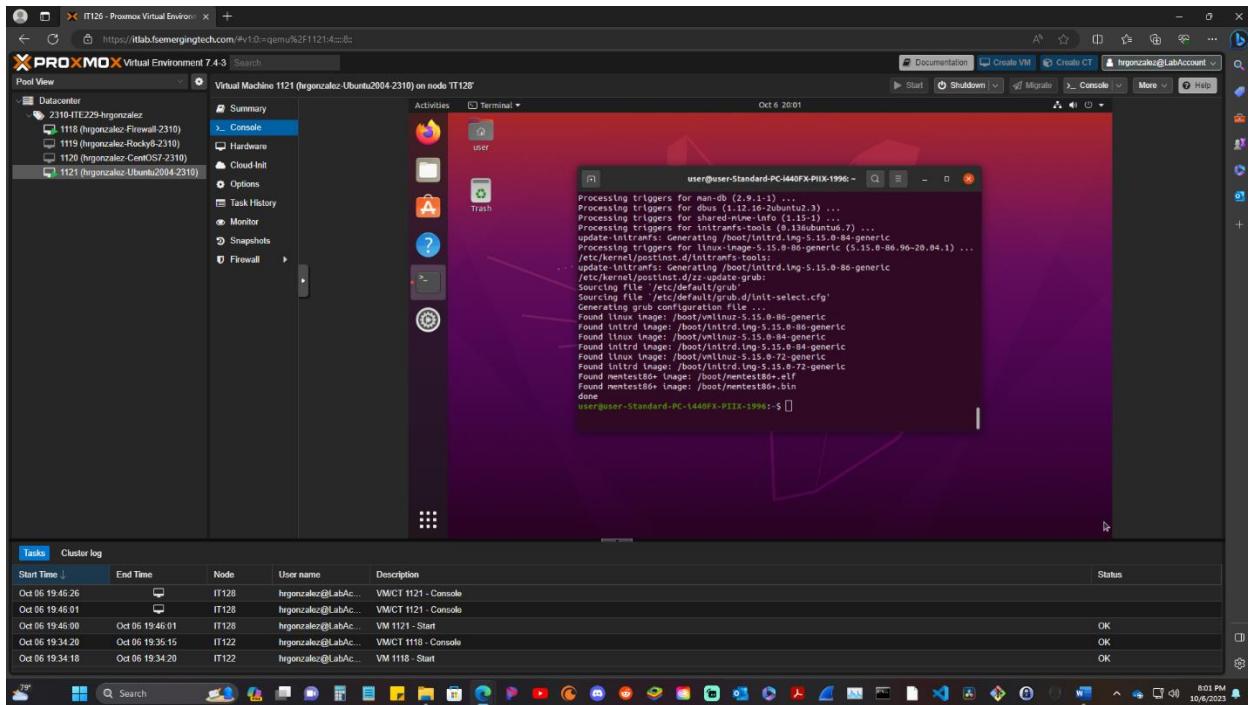

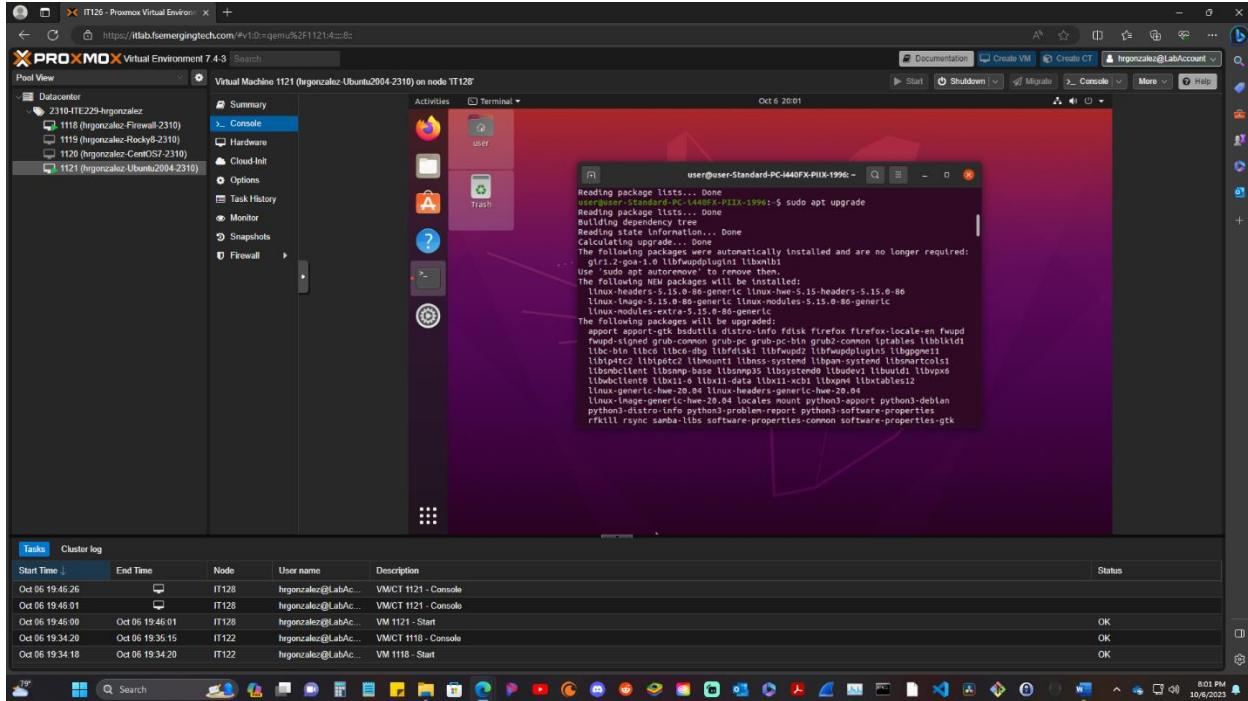

## Update Ubuntu

Open up Ubuntu Terminal and type command **sudo apt-get update** to update UBUNTU.

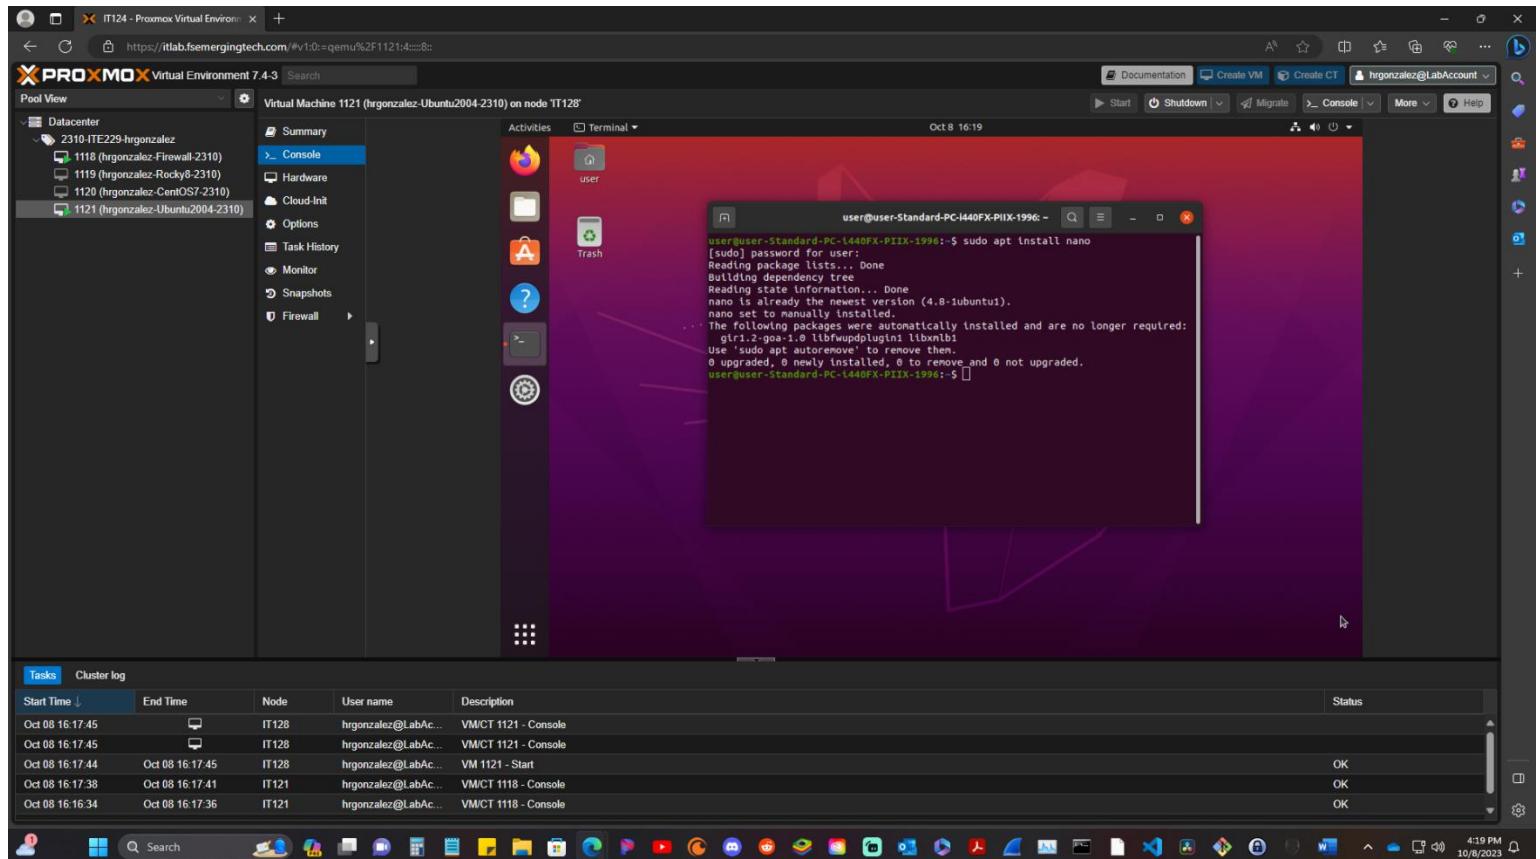

## Upgrade Ubuntu

Next type command `sudo apt upgrade` to upgrade all packages to the latest versions. \*When asked if you want to upgrade input `y` for yes, and it will upgrade all packages.

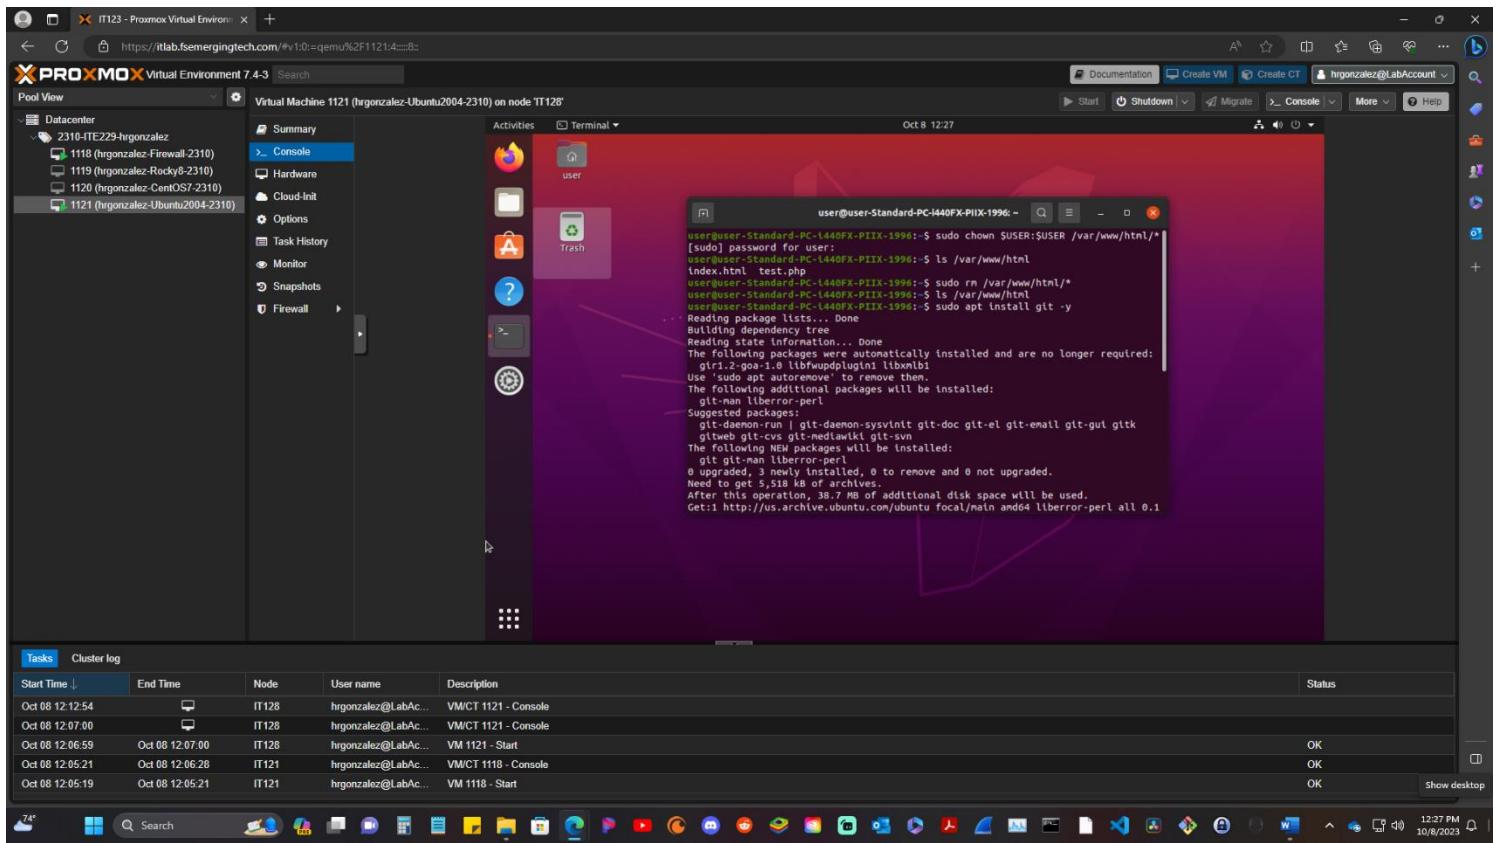

## Install Nano Editor

To install nano you need to enter command line **sudo apt install nano**. If it is not installed it will undergo the installation process. If it was previously installed they won't be any actions taken.

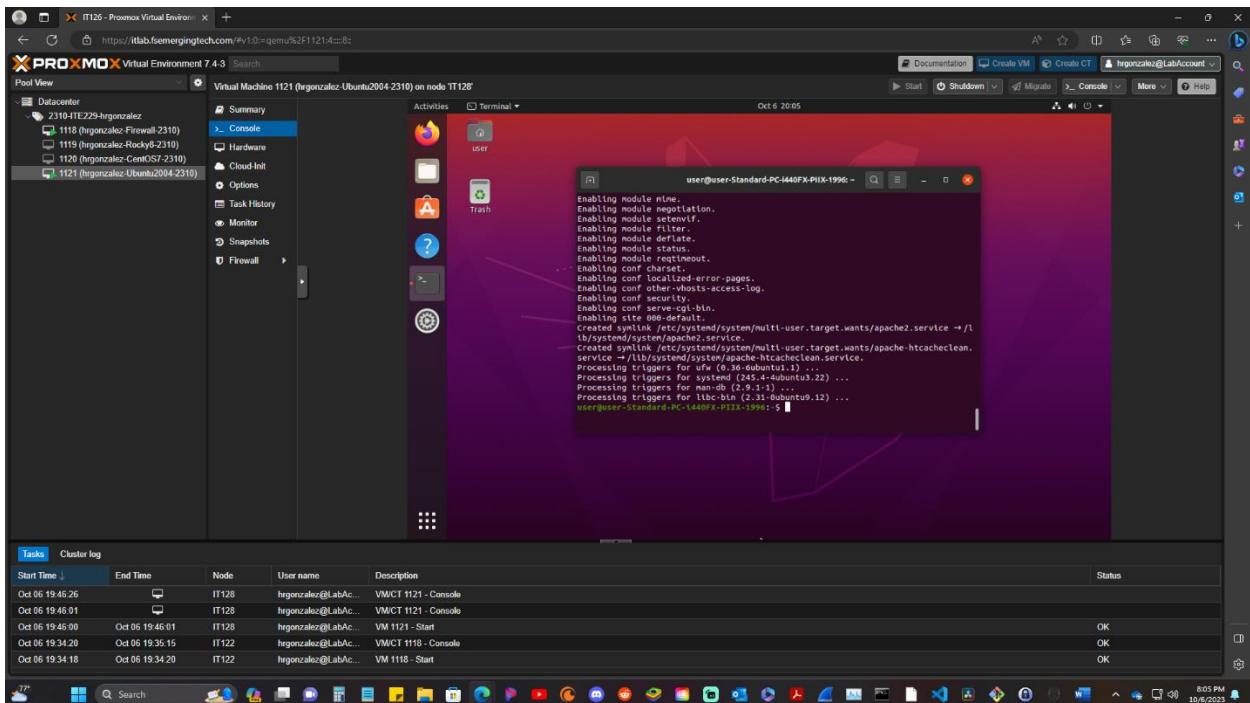

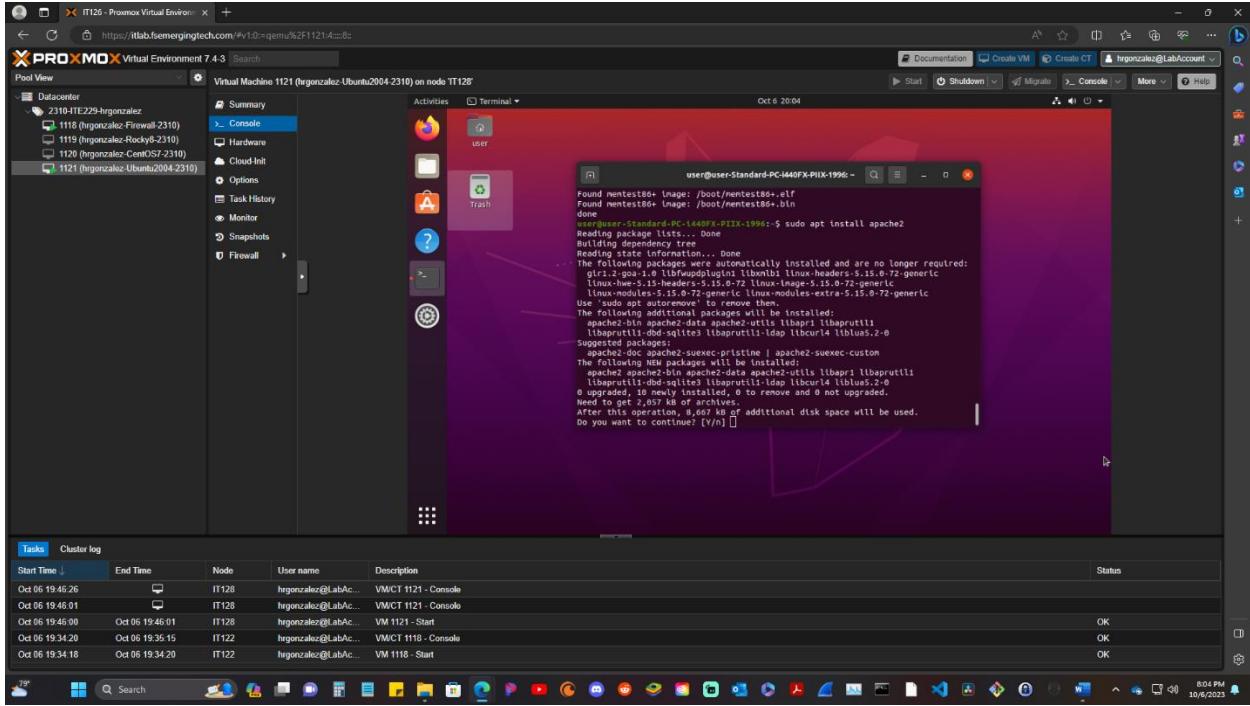

## Install Git

To install git you need to enter command line `sudo apt install git -y`. Wait until it completes installation before proceeding.

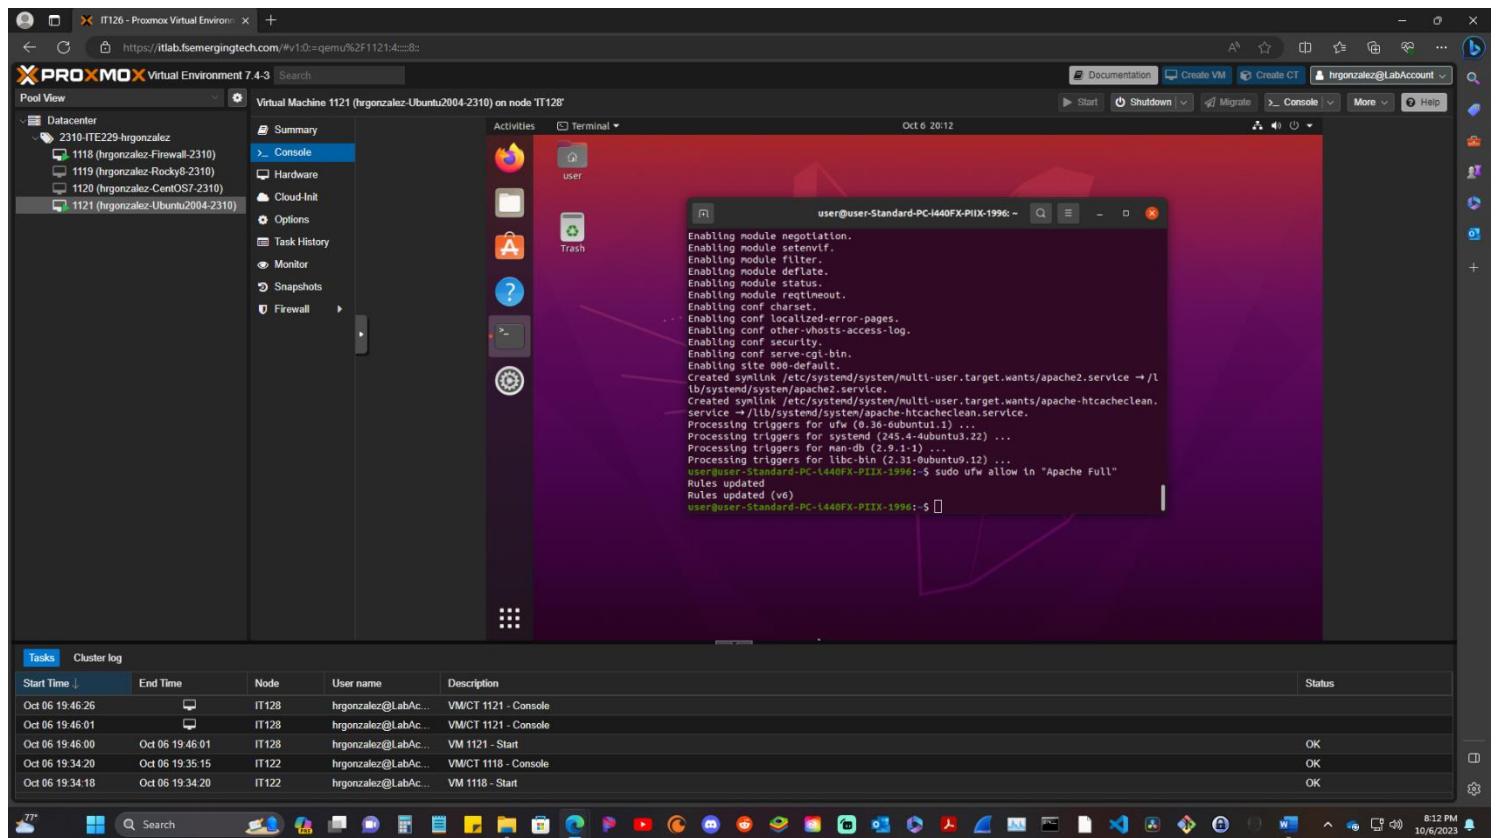

## Install Apache2

Enter command prompt sudo apt install apache2 to install Apache web server package. \*When asked if you want to continue input y for yes, and it will continue with the install.

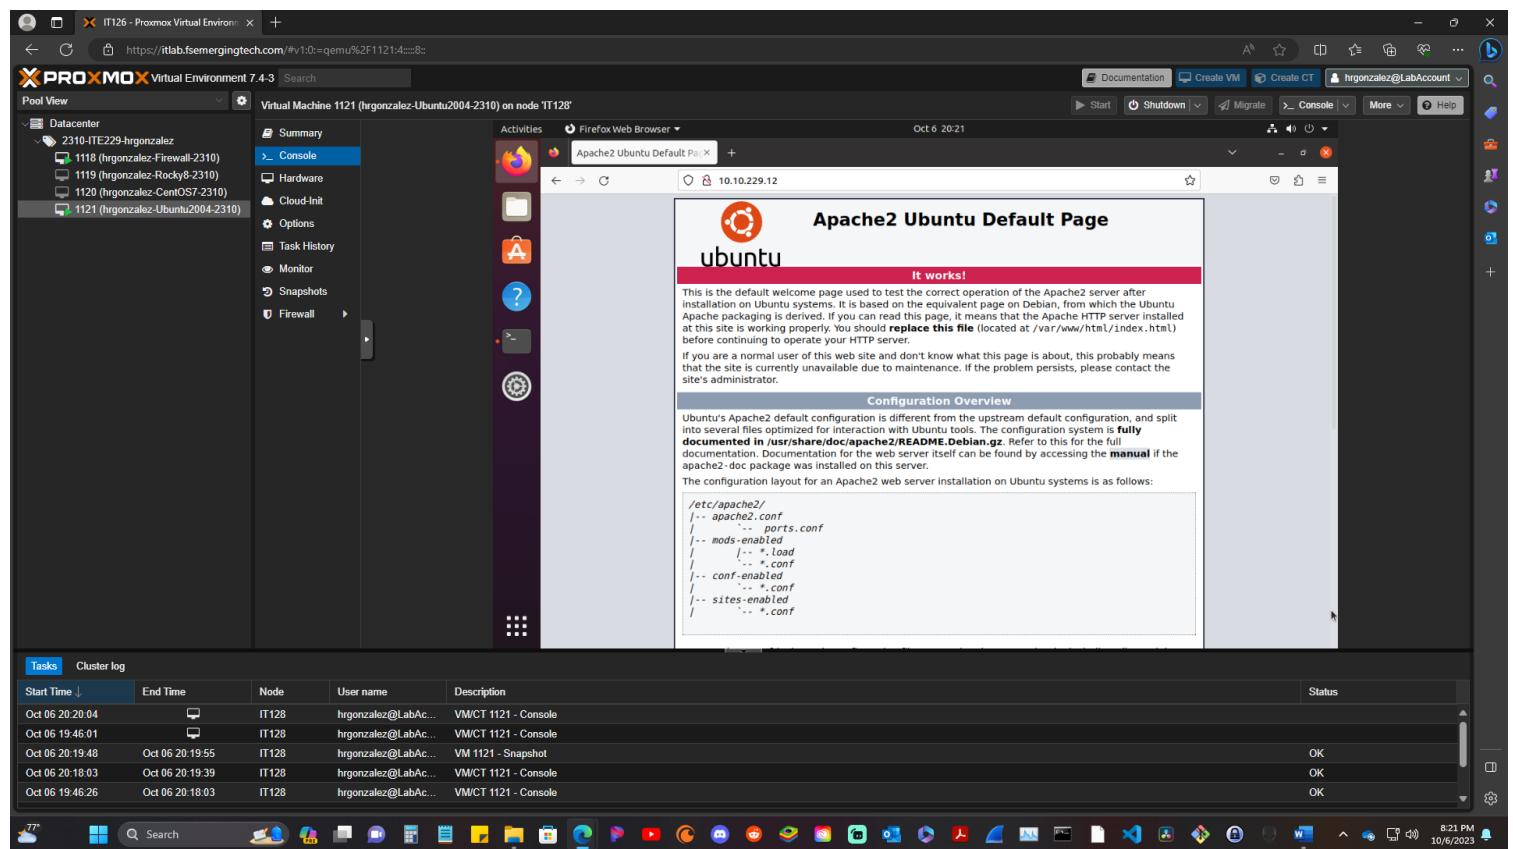

## Open Firewall Ports 80 and 443

Enter command prompt **sudo ufw allow in "Apache Full"** to allow TCP/80 and TCP/443 in, which are communication ports needed. This command will apply a firewall profile for Apache.

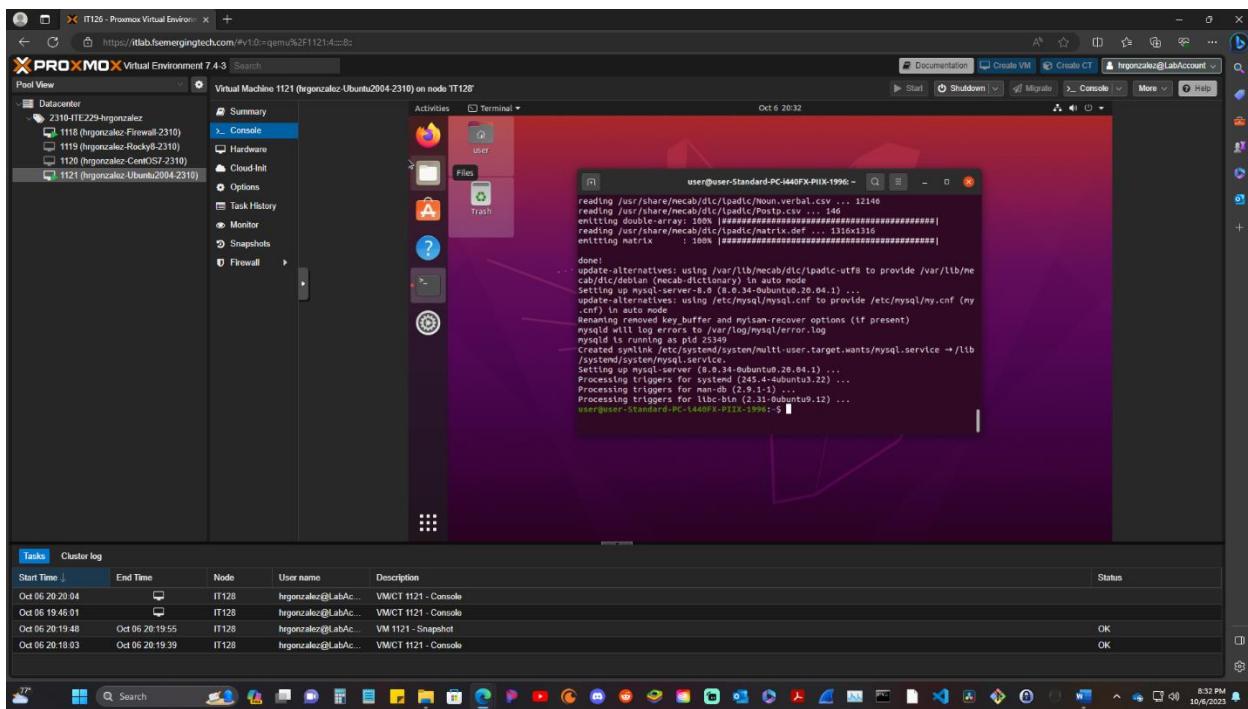

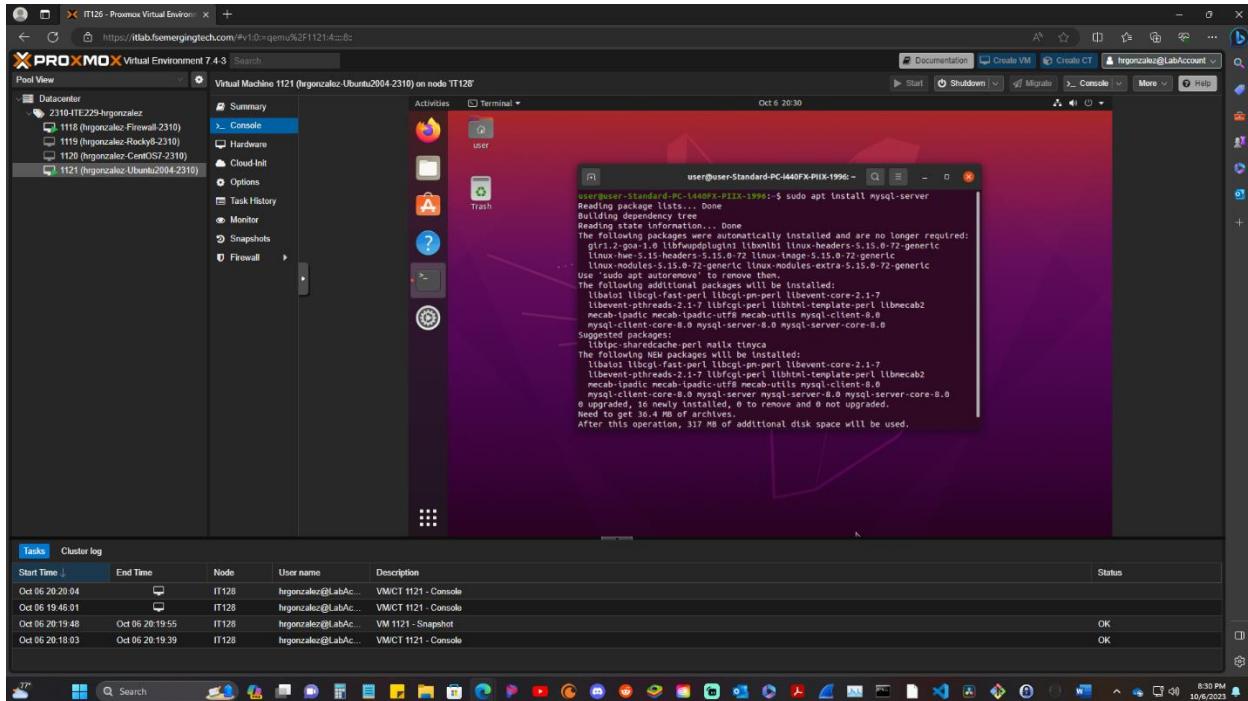

## Browse to Apache2 Ubuntu Default Page

Next open up fire fox web browser in Ubuntu and browse to <http://10.10.229.12> and make sure your installation was successful. You should see a page like the one below.

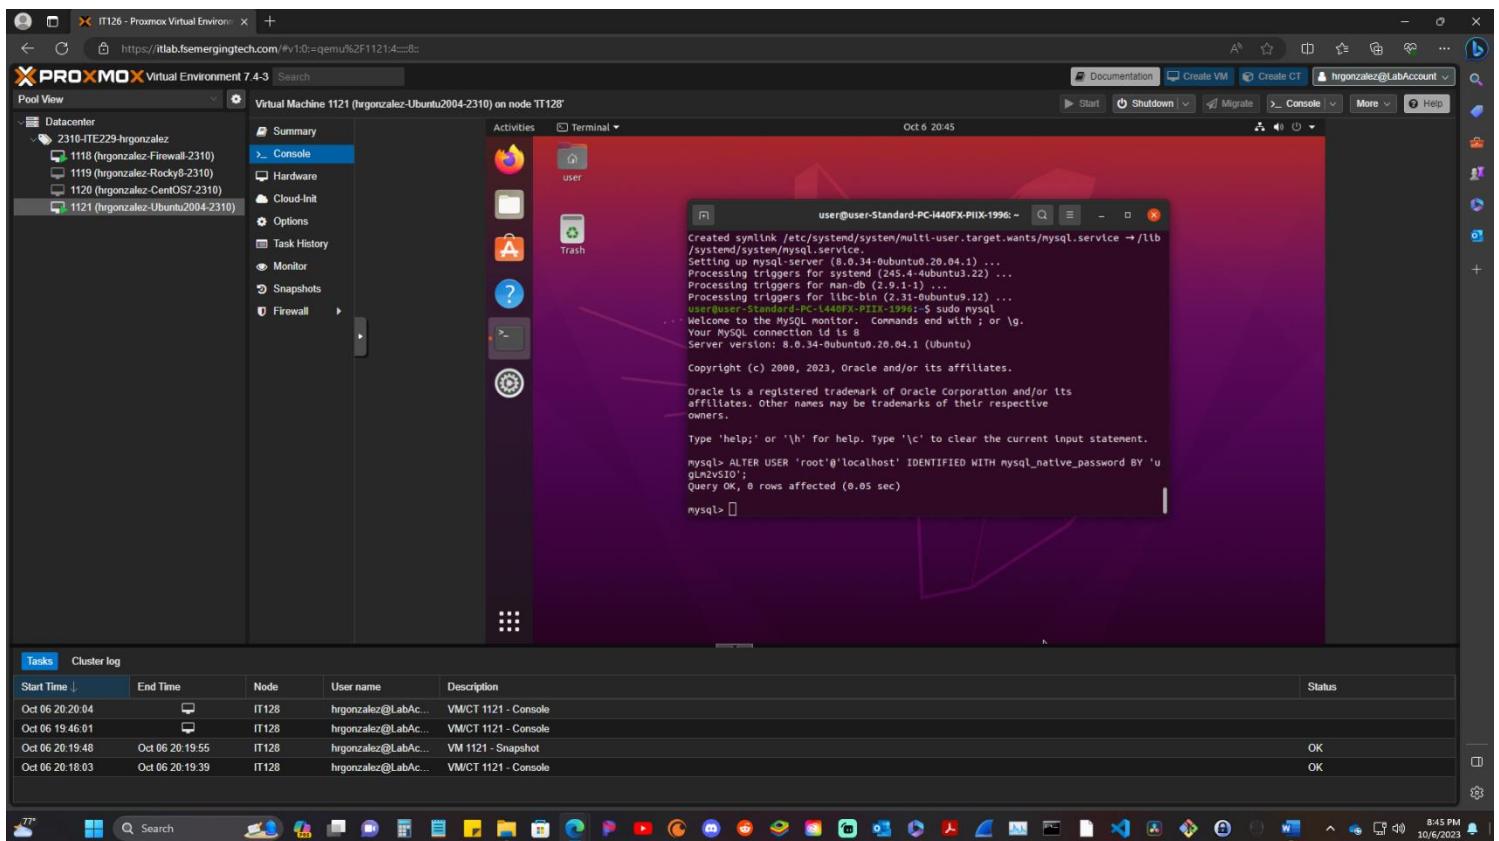

## Install MySQL

Now we need to install MySQL. Input command `sudo apt install mysql-server`. When asked to continue enter **Y** for yes, and then wait until install is completed.

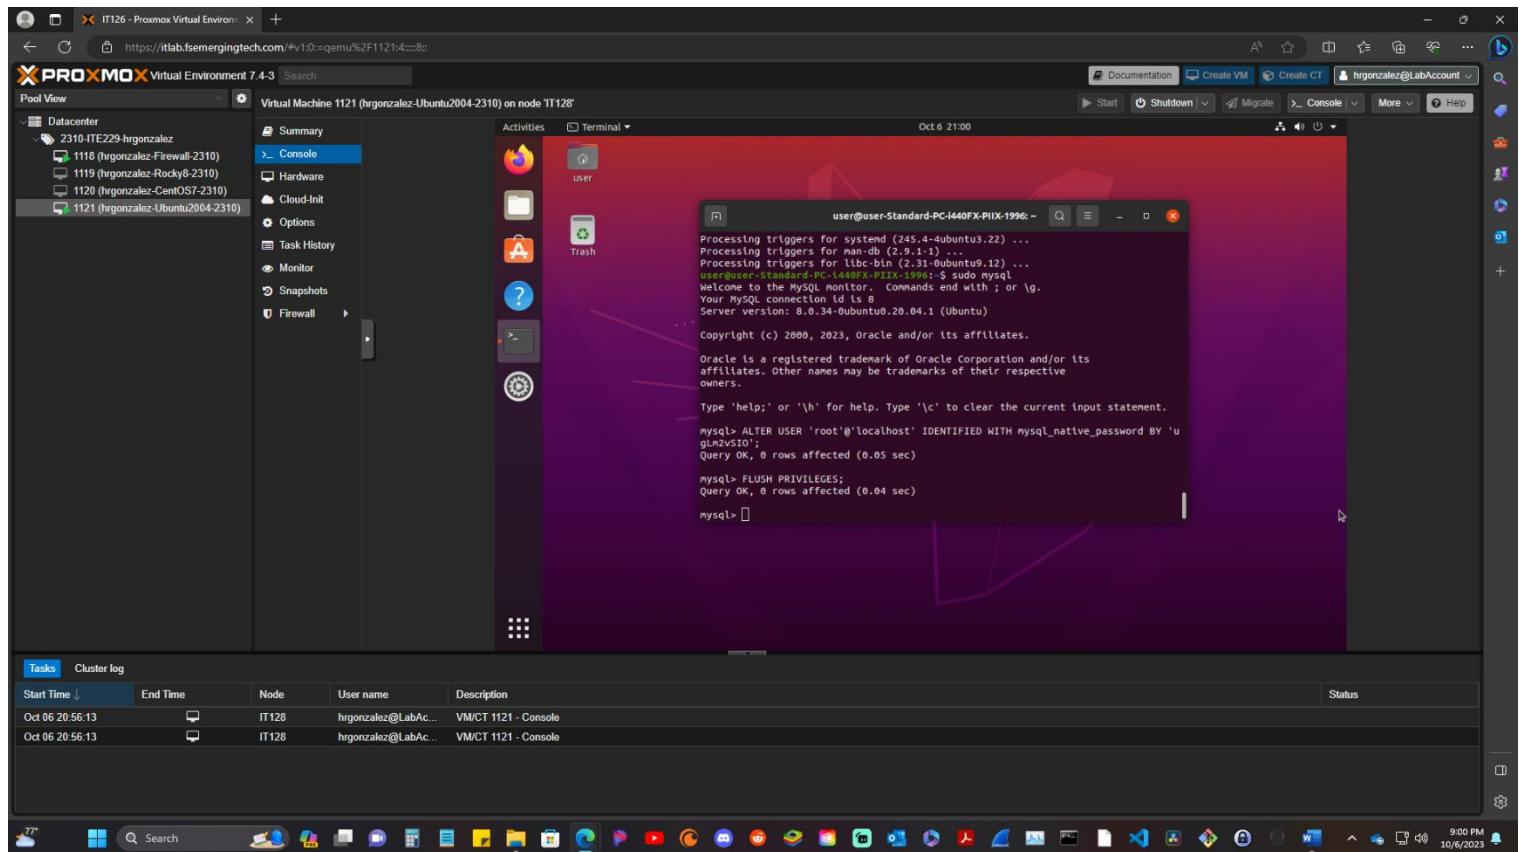

## Alter root user password

Next we need to change our MySQL password, but before we do that you can use a password generator or make your own password (**be sure to save this password somewhere safe this is the password we are going to use for MySQL**). Enter command line `sudo mysql`. This will bring you to the MySQL command line. Here we are going to enter command line `ALTER USER 'root'@localhost' IDENTIFIED WITH mysql_native_password BY 'newpasswordhere';` then hit enter. If input correctly you should see Query Ok.

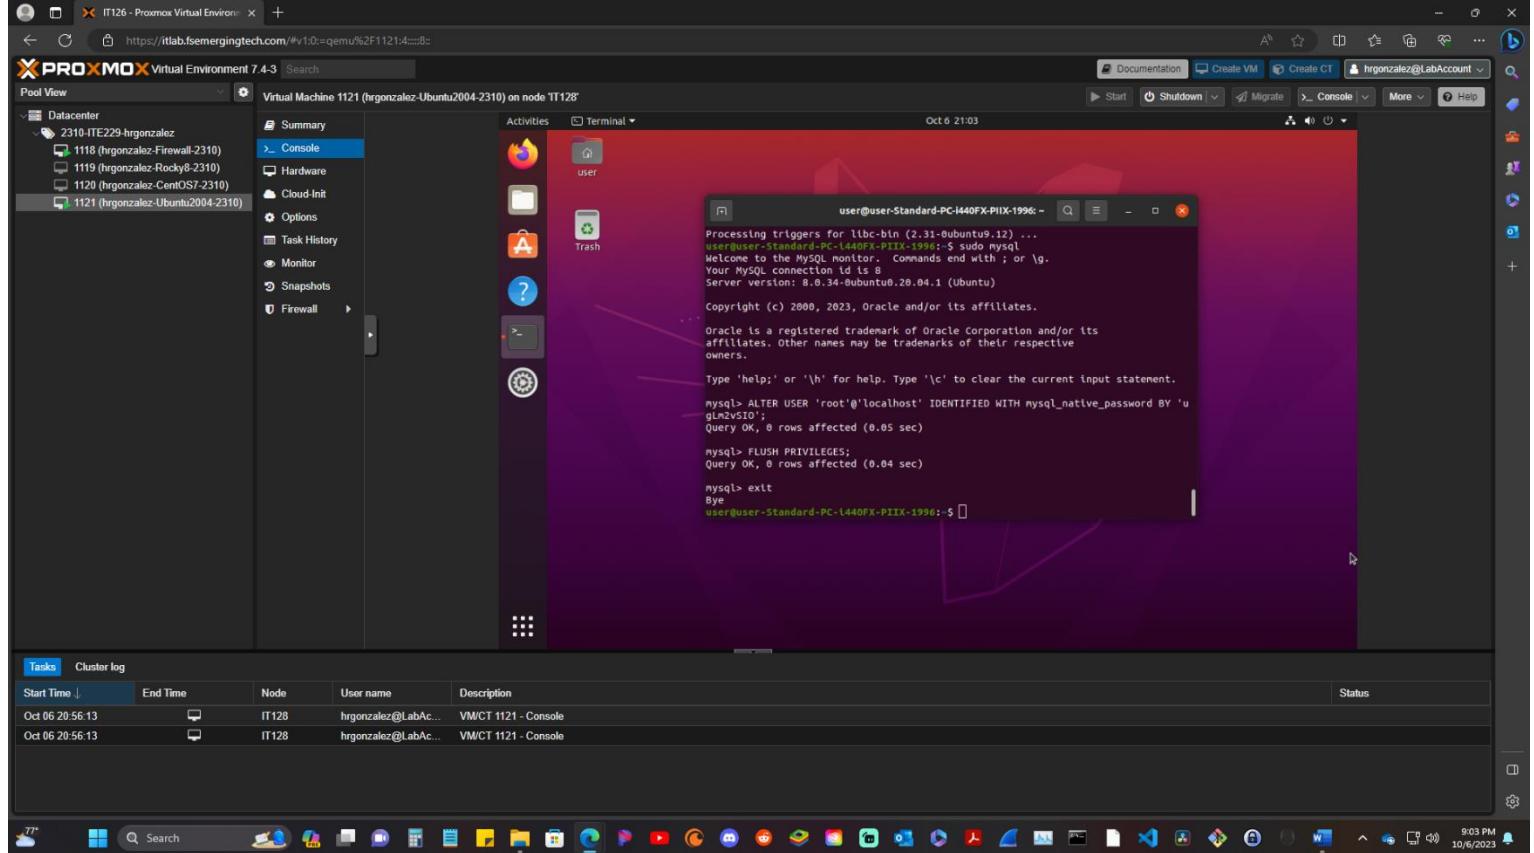

## Flush Privileges

After we need to flush to reload the settings. Enter command line **FLUSH PRIVILEGES;** then hit enter. If prompt correctly you will see Query ok.

## Quit MySQL

Now we need to exit out of My SQL. Enter command line `exit`. If correct it will redirect you to your username `user@user`. \*Make sure to document password used for MySQL.

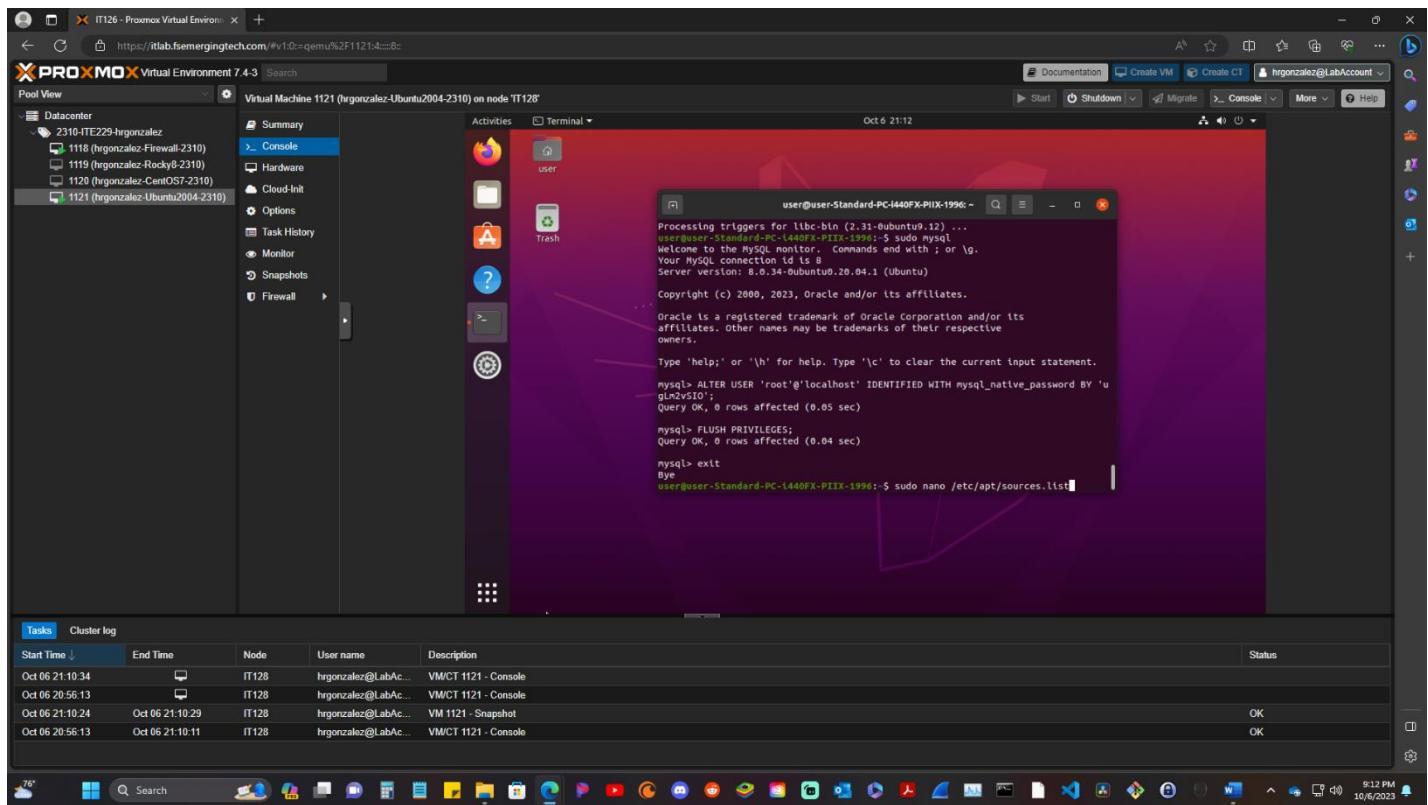

## Install PHP

Edit Sources.list File

Add “universe” to all URLs

We need to enable Ubuntu universe repositories, because some of the PHP packages for WordPress require it. In the terminal enter command line `sudo nano /etc/apt/sources.list`. We need to add `universe` to all the URLs. Follow picture below and mimic it. After hit control key, save changes, and then hit enter. It should take you back to the username `user@user` if done correctly.

## Update Ubuntu (refreshes the repolist)

Next, we need to update/refresh/enable repolist that we just changed. To do this enter command line **sudo apt update** and wait until it completes.

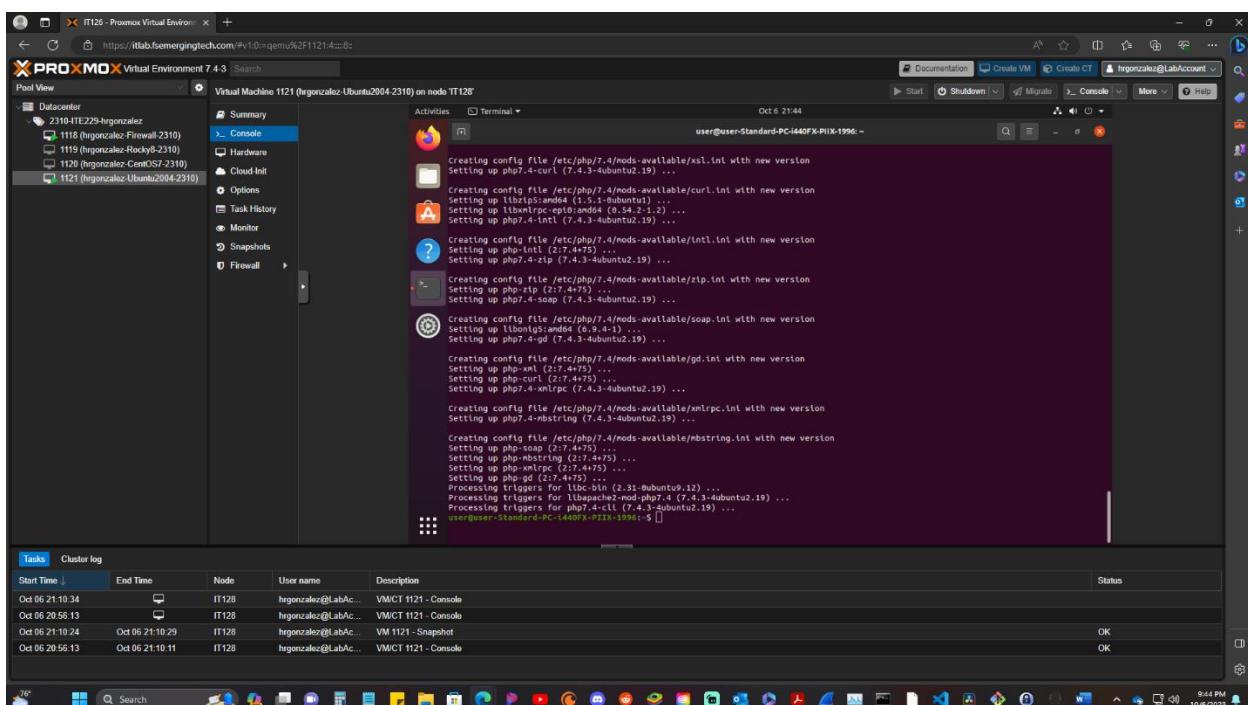

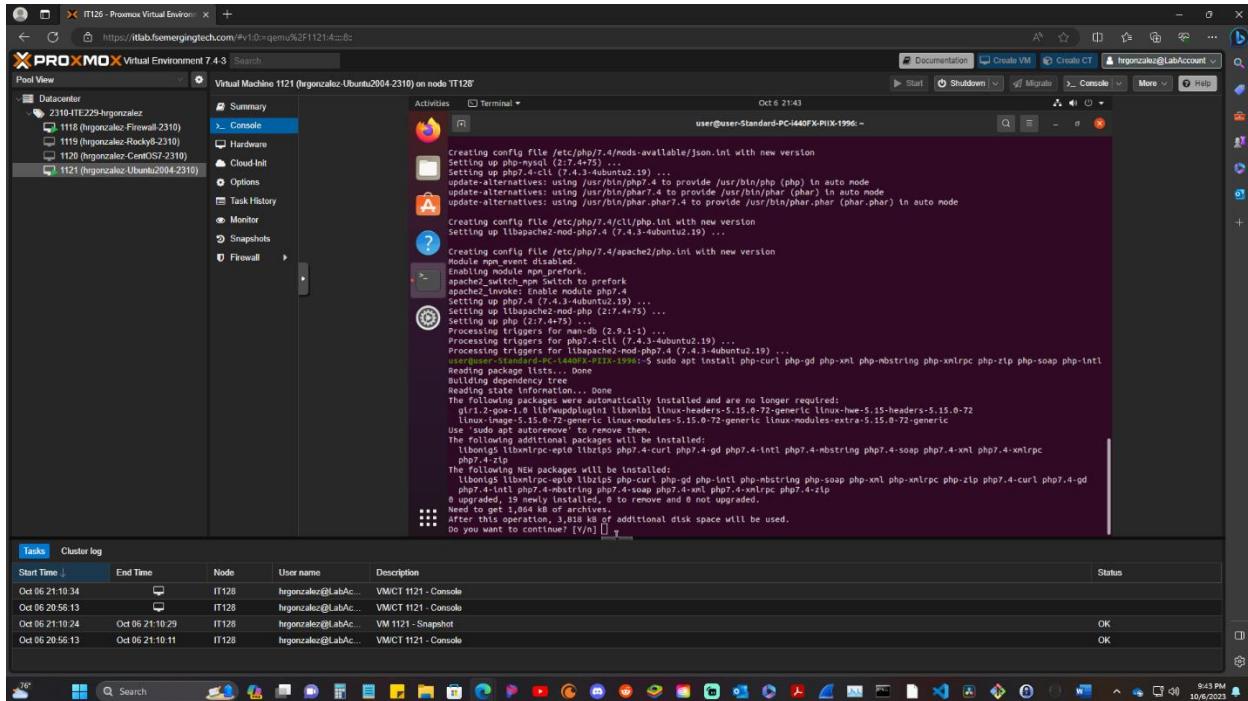

## Install Required PHP Libraries

To do this enter command line `sudo apt install php libapache2-mod-php php-mysql`. Then input Y and hit enter to continue. Wait until it finish installs. This will install PHP base libraries.

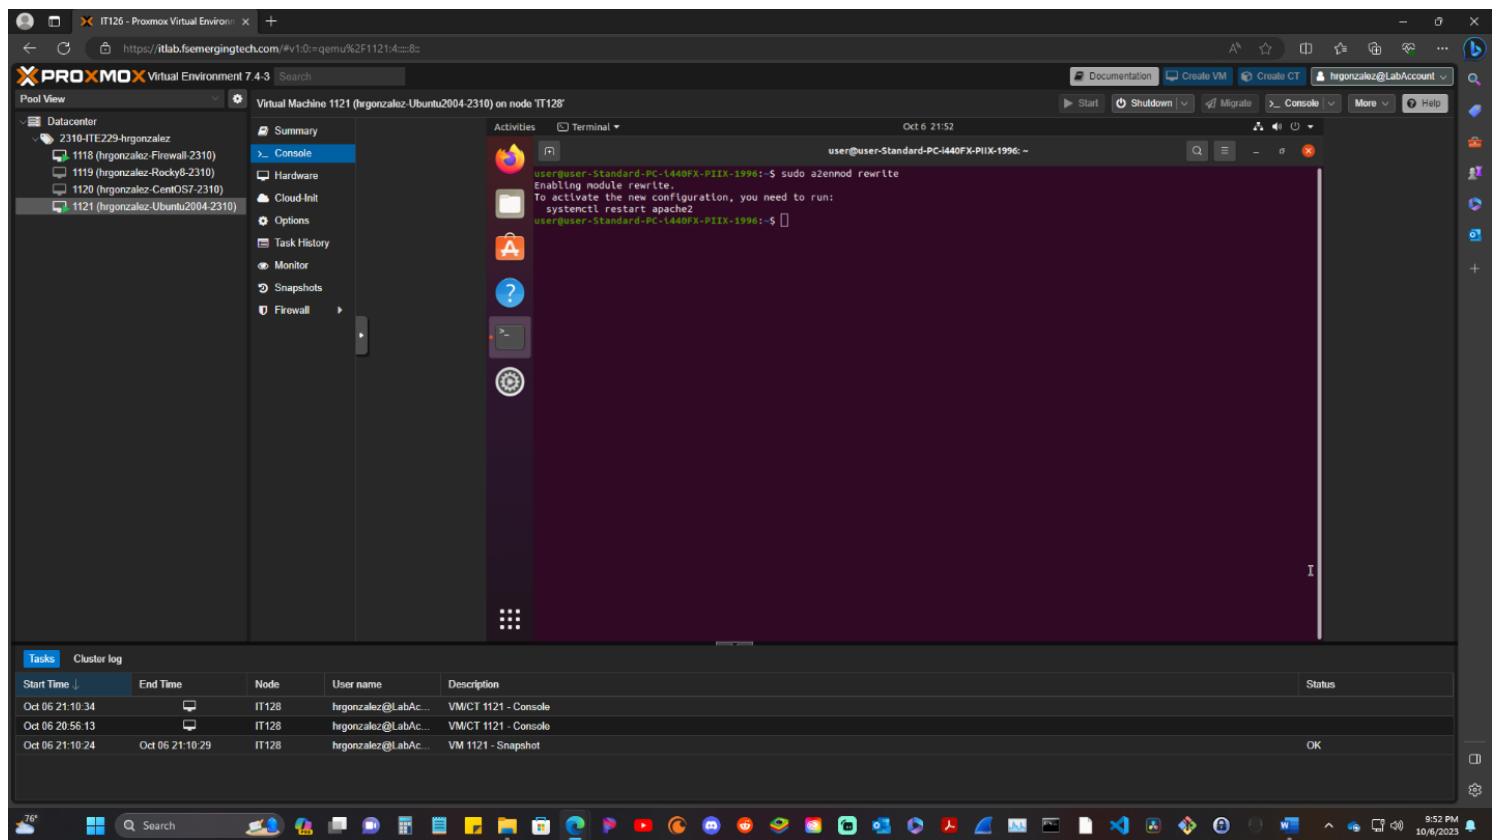

## Install Required MySQL Libraries

Now we need to install MySQL libraries required by Wordpress. Enter command line `sudo apt install php-curl php-gd php-xml php-mbstring php-xmlrpc php-zip php-soap php-intl` then hit enter. After input Y and hit enter to continue and wait for completion of installed.

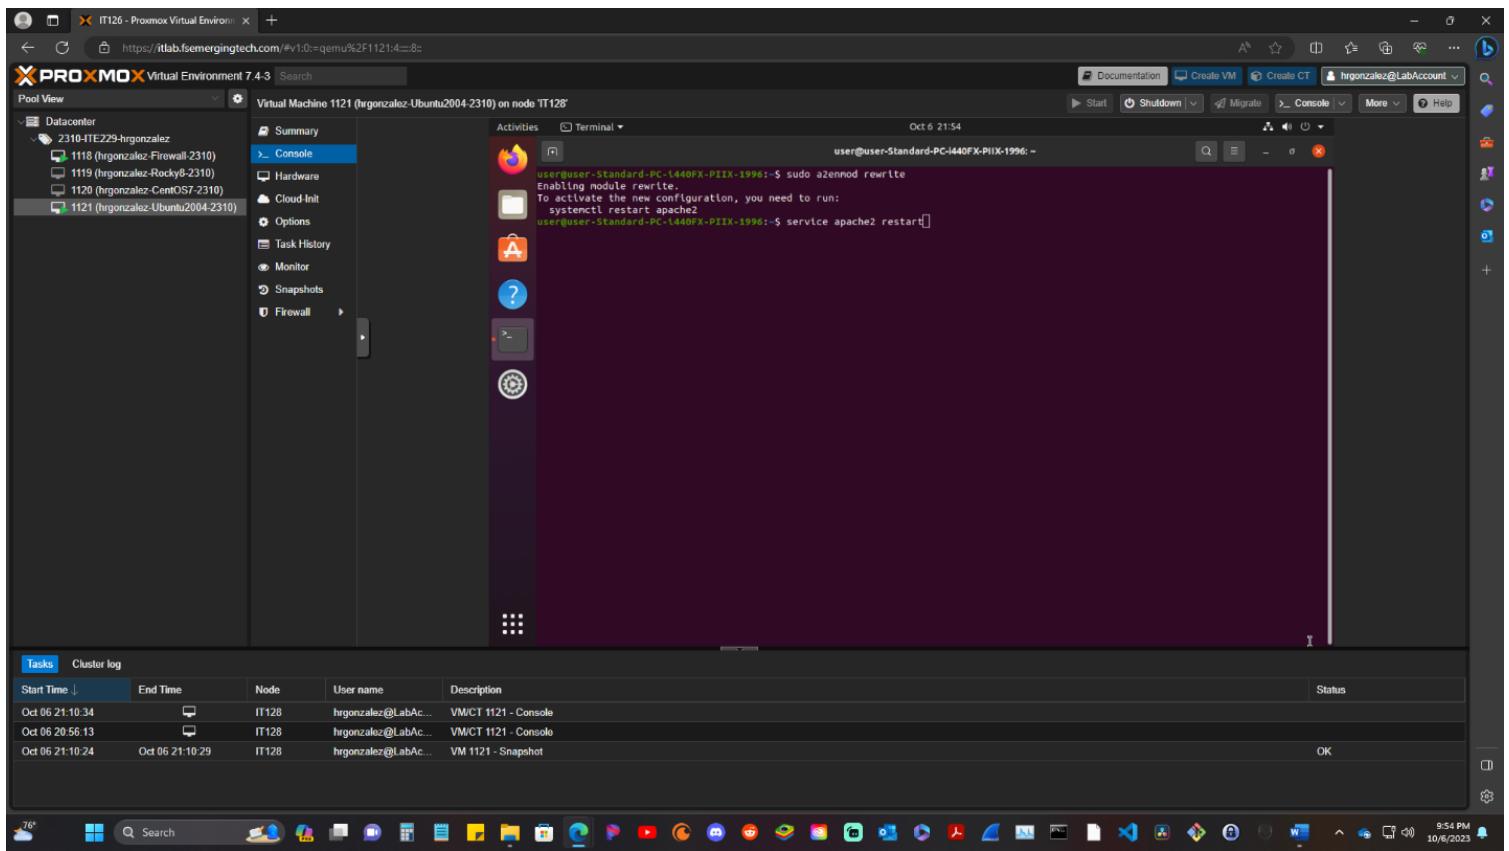

## Enable URL Rewrites (clean URLs)

Then we need to enable URL rewrites which gives you the ability to enter clean URL without those long outputs that shows question marks, numbers, etc. To do this we need to enter command line **sudo a2enmod rewrite**.

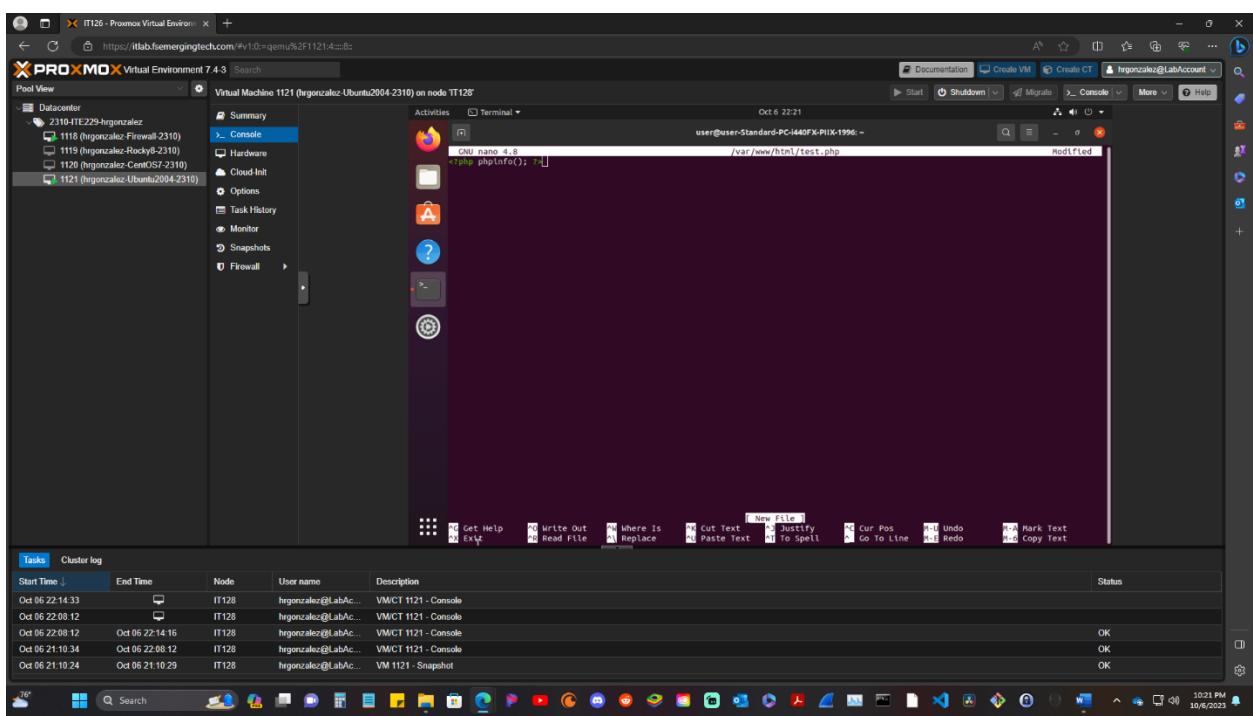

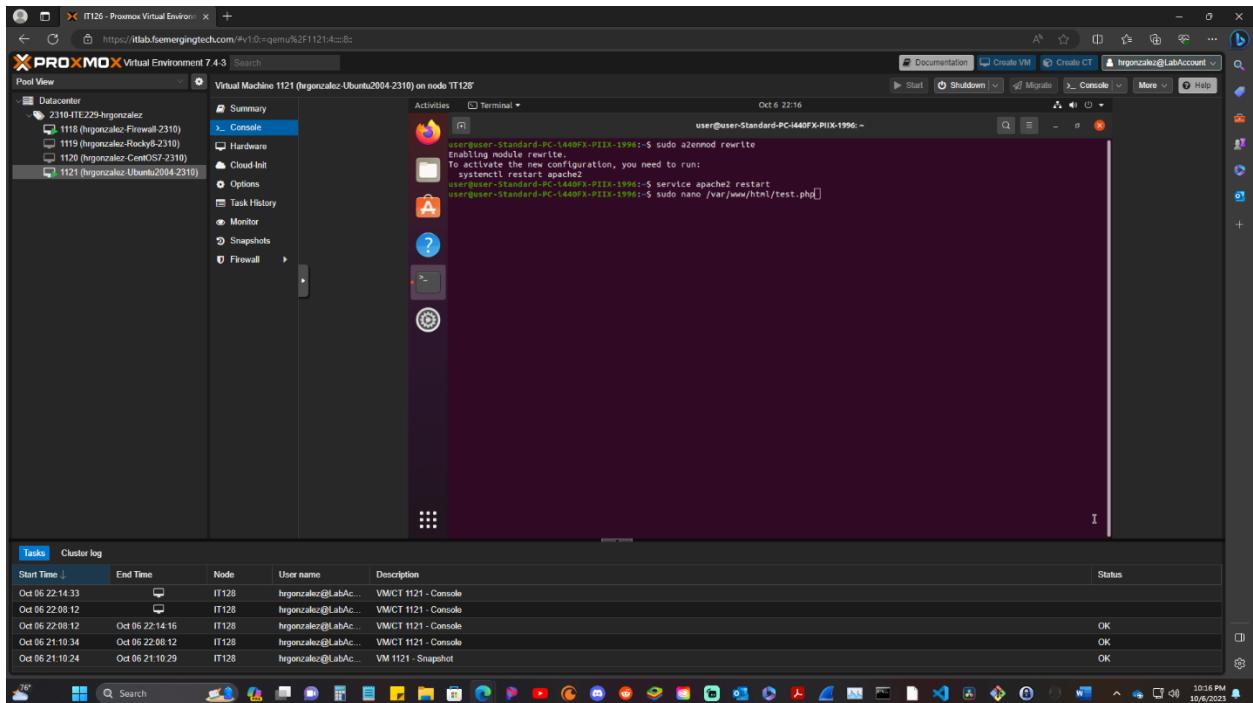

## Restart Apache Service

Now we need to restart the Apache service. We can do this 2 ways. One we can enter command line sudo systemctl restart apache2 or we can use command line service apache2 restart. We are going to use command line service apache2 restart. Enter command line **service apache2 restart**. In the pop up window enter your **username password** then hit **authenticate**. It should bring you back to the terminal window with a new command line ready to be entered.

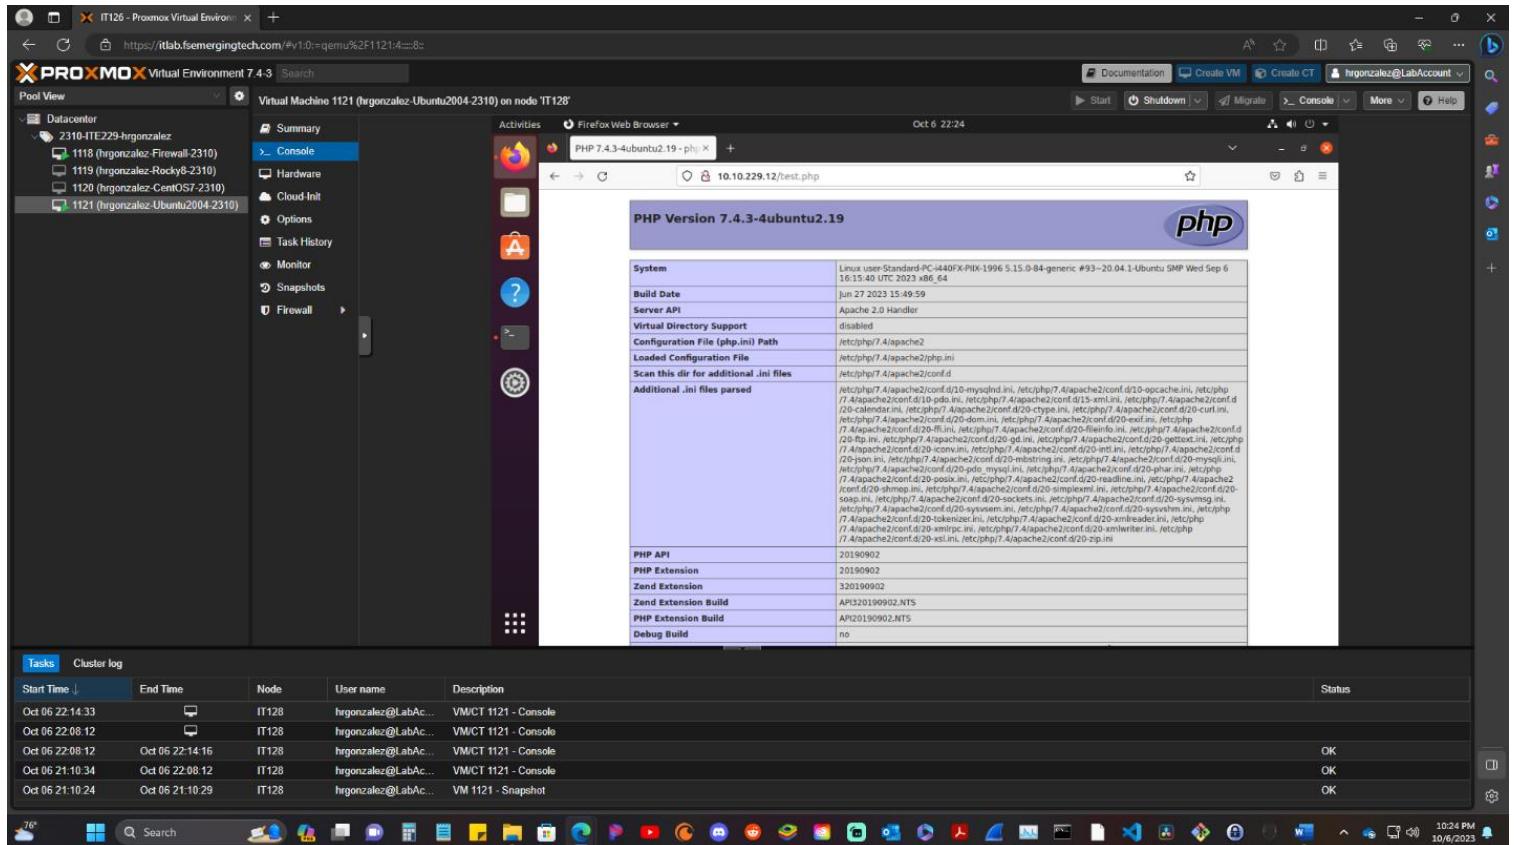

## Create a test.php Web Page

Now we need to create a test.php page. In order to do this you need to enter command line `sudo nano /var/www/html/test.php`. This will open a blank nano page. Here we are going to write `<?php phpinfo(); ?>`, which is basically saying to pull up php information page. After exit by hitting **control x** to exit, then **save file** and **hit enter**. This should take you back to your username line.

## Test the test.php Web Page

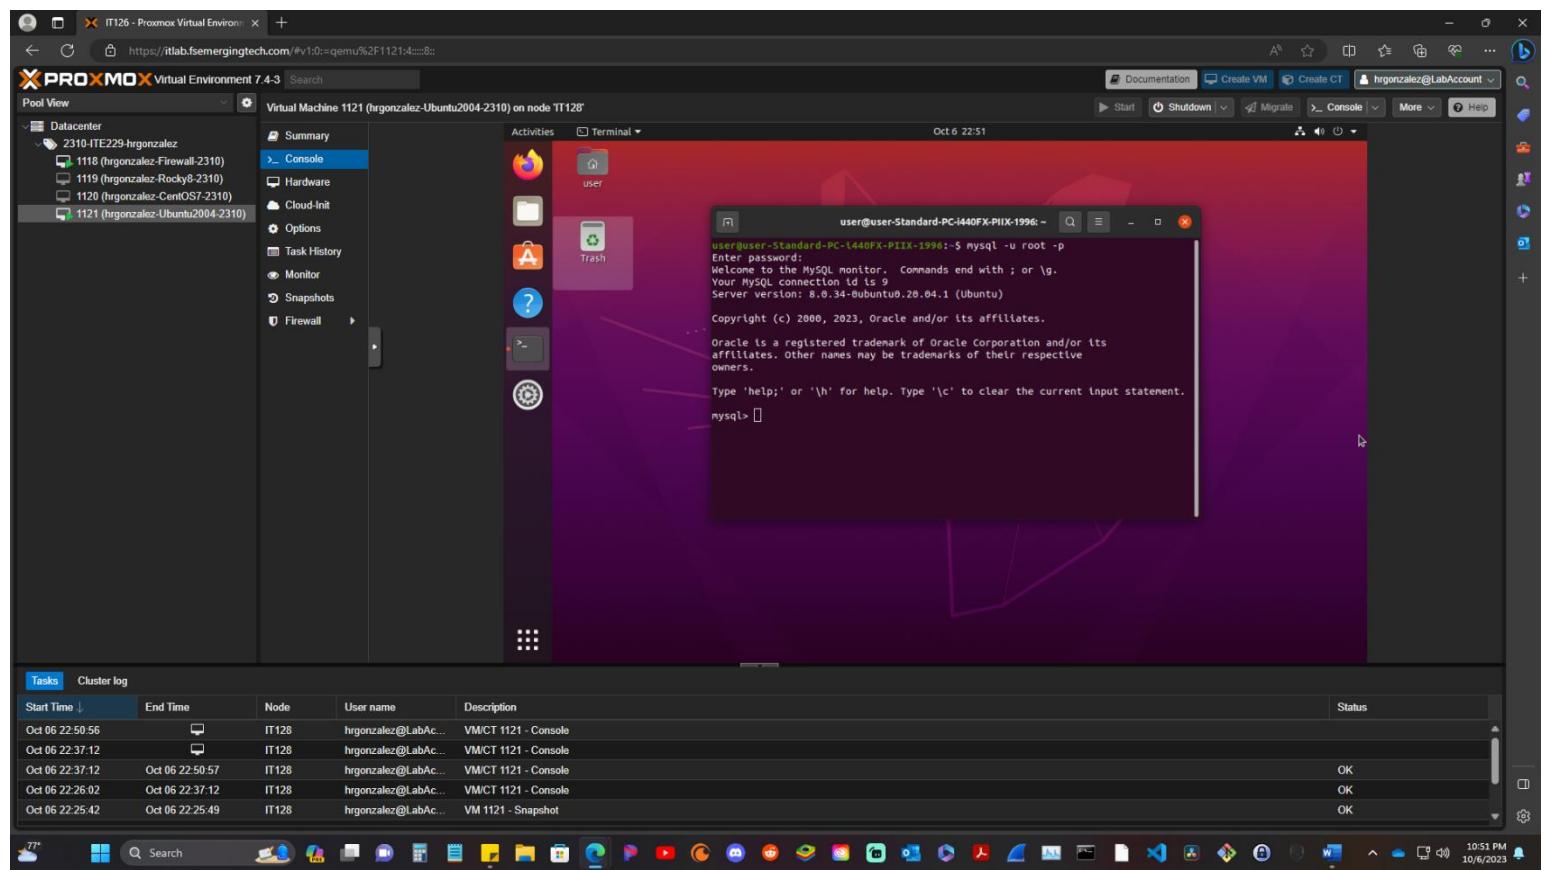

Now we need to test the page. Open up **firefox web browser** in your Ubuntu. Enter **10.10.229.12/test.php** on the url. You should see a picture like the one below if installed and done correctly. This is the php information page.

## Database Configuration in MySQL

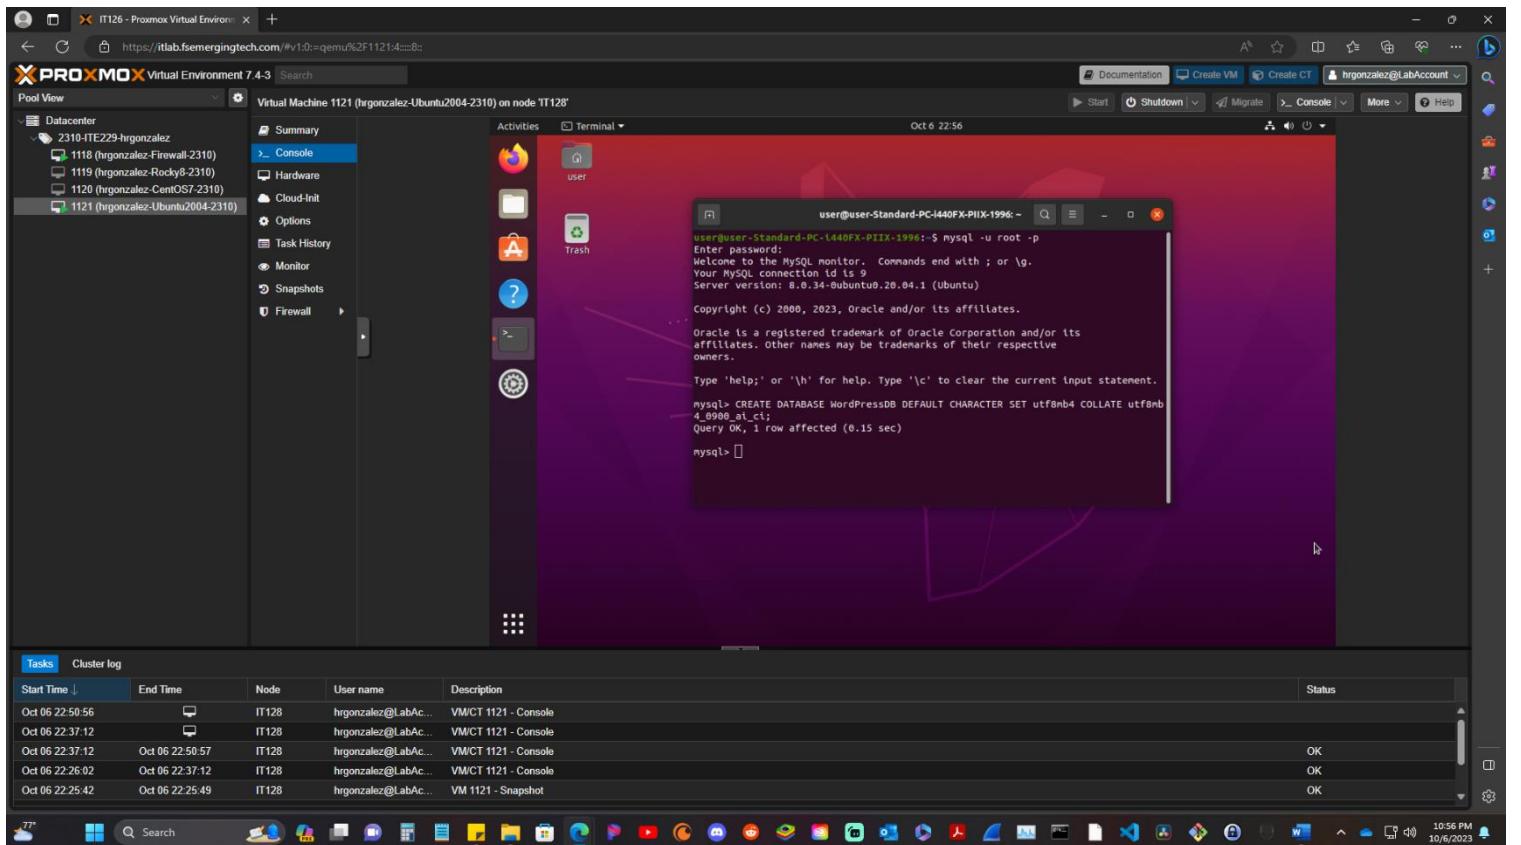

### Log into MySQL Database

We need to log in to MySQL CLI. To do this enter command line `mysql -u root -p`. Then enter **the password that was generated** in previous step. This should take you to MySQL database.

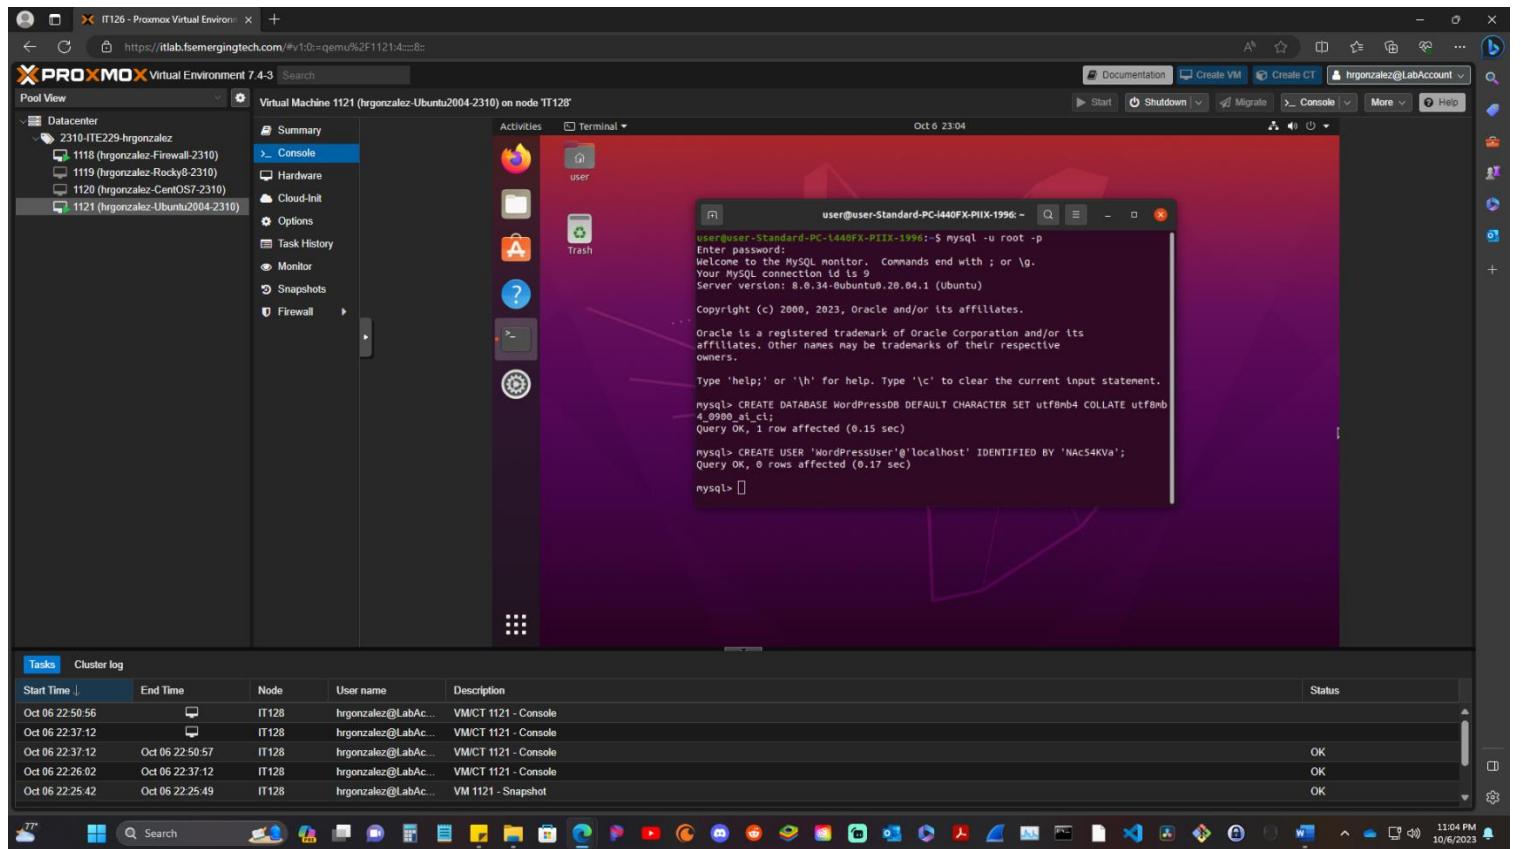

## Create WordPress Database in MySQL

Inside MySQL Database we are going to create a WordPress database. In MySQL CLI enter **CREATE DATABASE WordPressDB DEFAULT CHARACTER SET utf8mb4 COLLATE utf8mb4\_0900\_ai\_ci;** then hit enter.

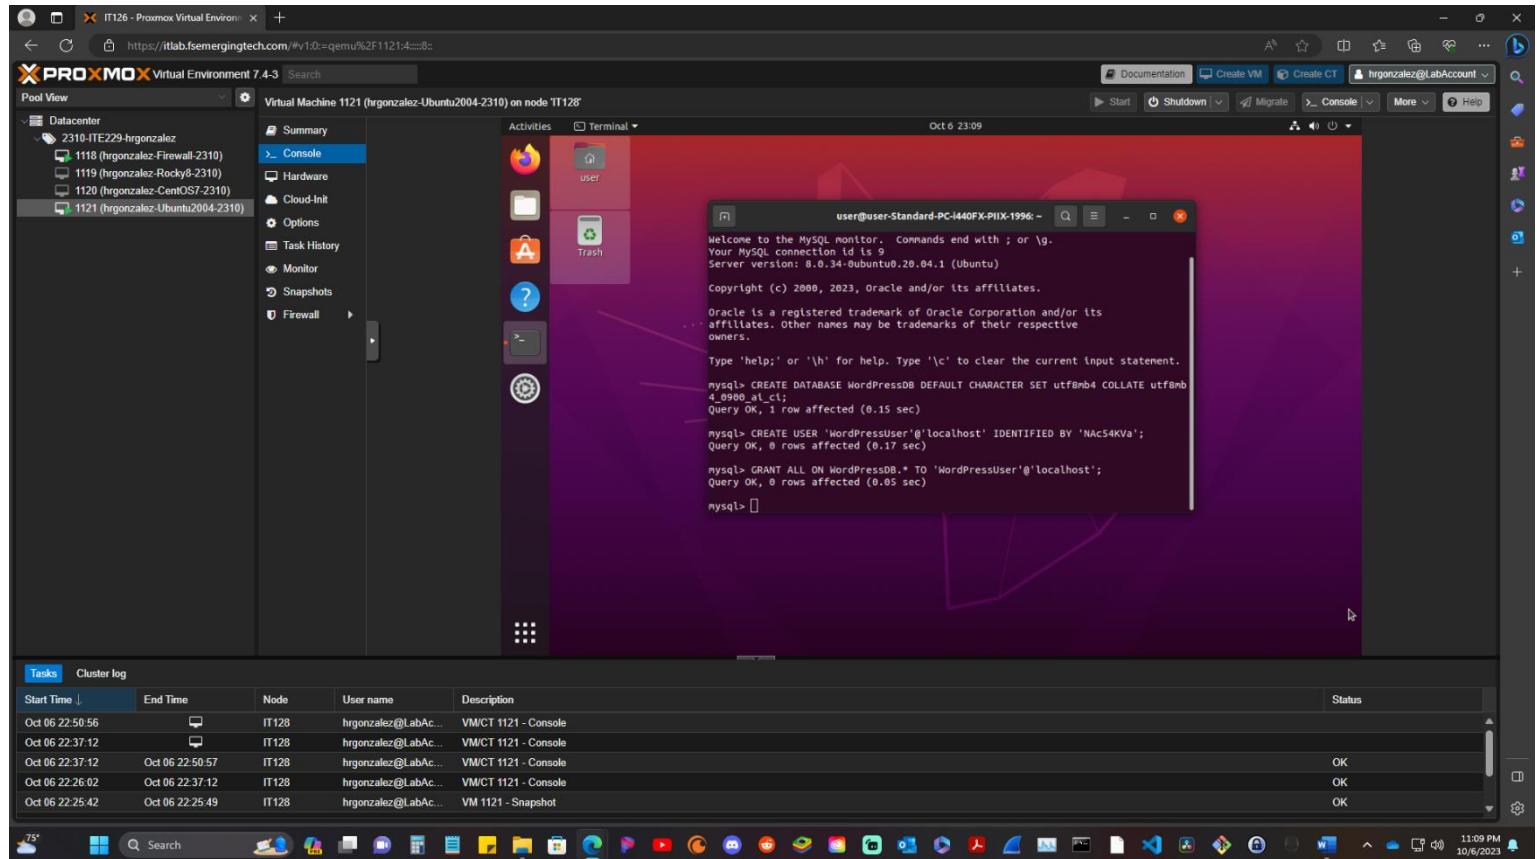

## Create WordPress User for MySQL Database

Next step is to create a WordPress “User” for MySQL Database. We are going to create a new password for WordPress User. Create one and save it just like in the previous step (we are going to need it for this step). In the next MySQL line enter **CREATE USER ‘WordPressUser’@‘localhost’ IDENTIFIED BY ‘yournewpasswordhere’**; then hit enter. This will create the User.

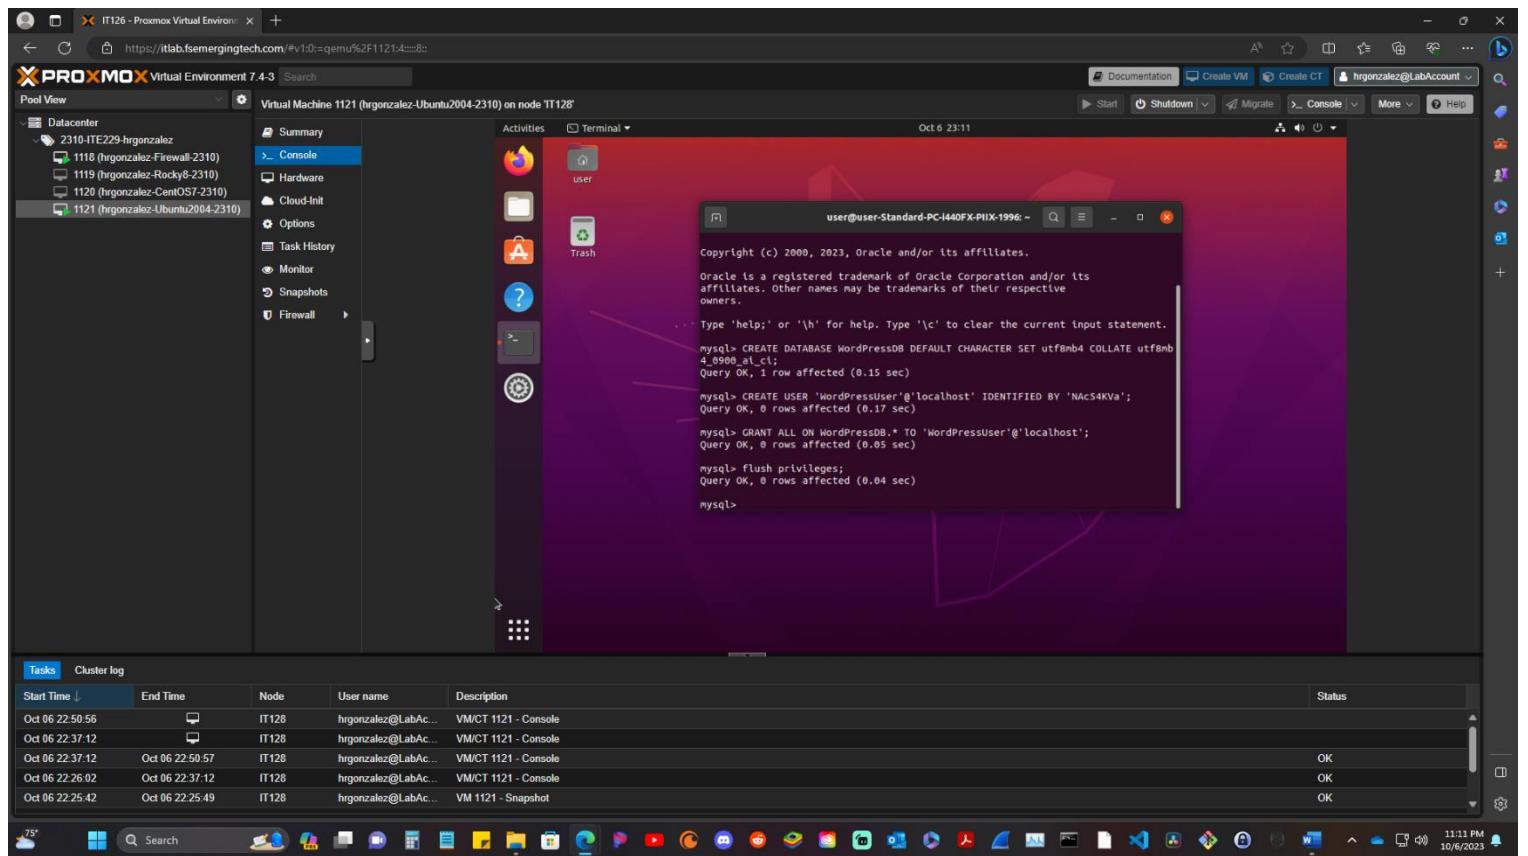

## Grant Privileges to this New WordPress User

Now we need to grant permission to this new user. In the MySQL command line enter **GRANT ALL ON WordPressDB.\* TO 'WordPressUser'@'localhost'**; This will enable permissions.

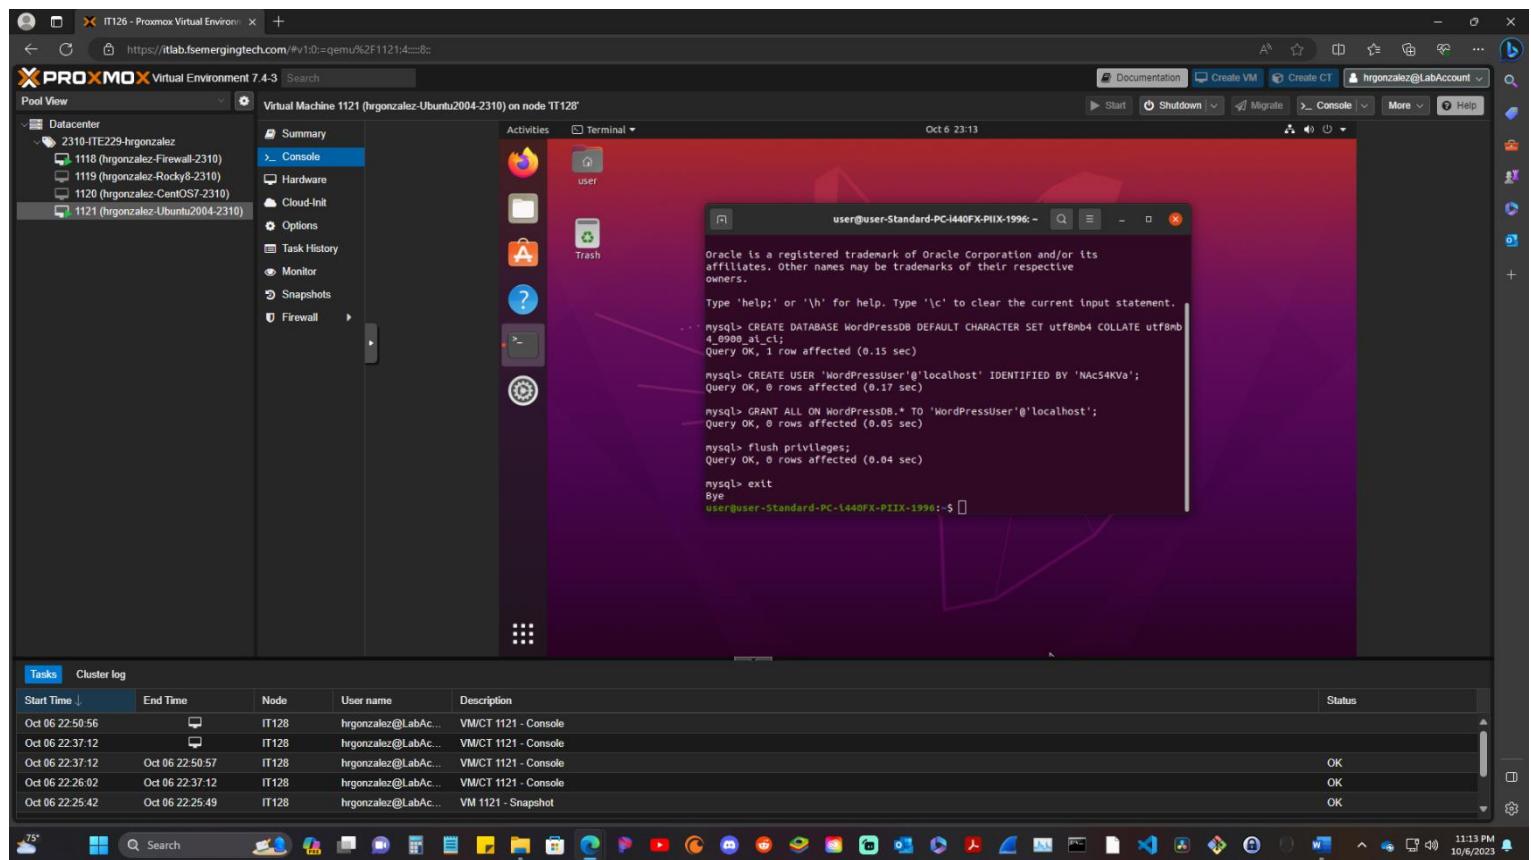

## Flush Privileges

Now is time to flush the Privileges. In the MySQL command line enter **flush privileges;**

## Quit MySQL

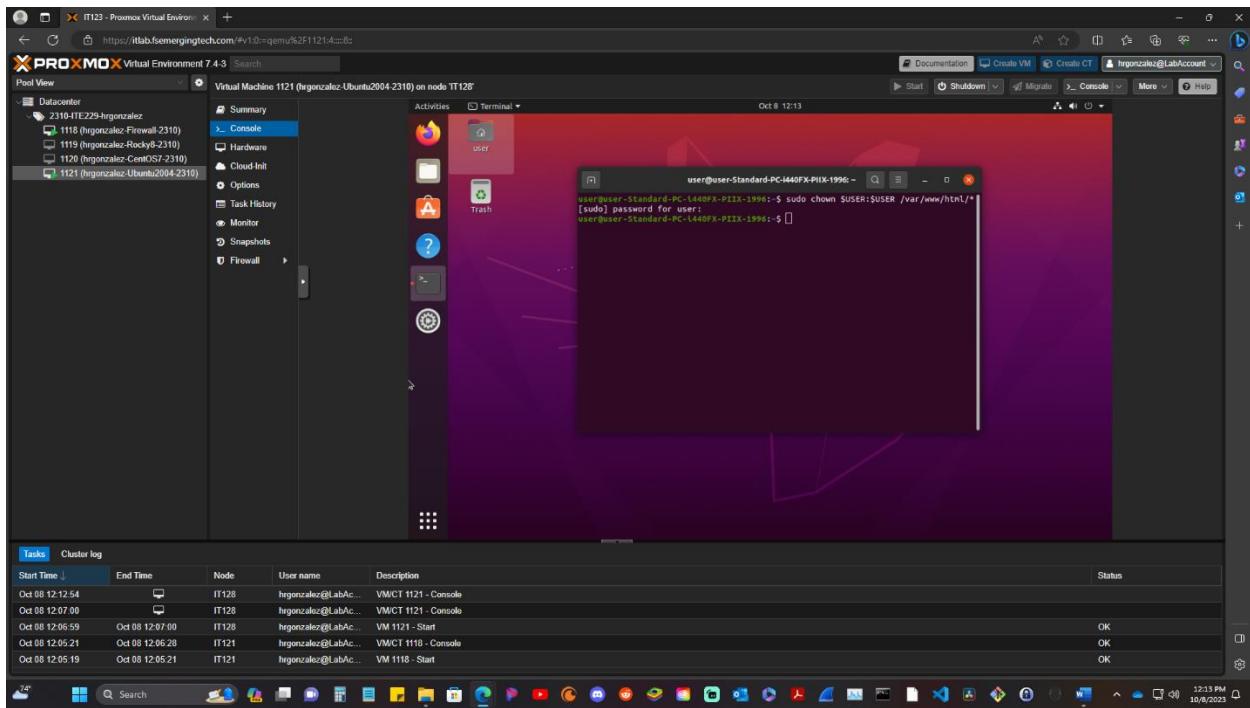

We are done with MySQL. To exit MySQL in the MySQL command line enter **exit**. You should return back to the **username user**.

## Install WordPress

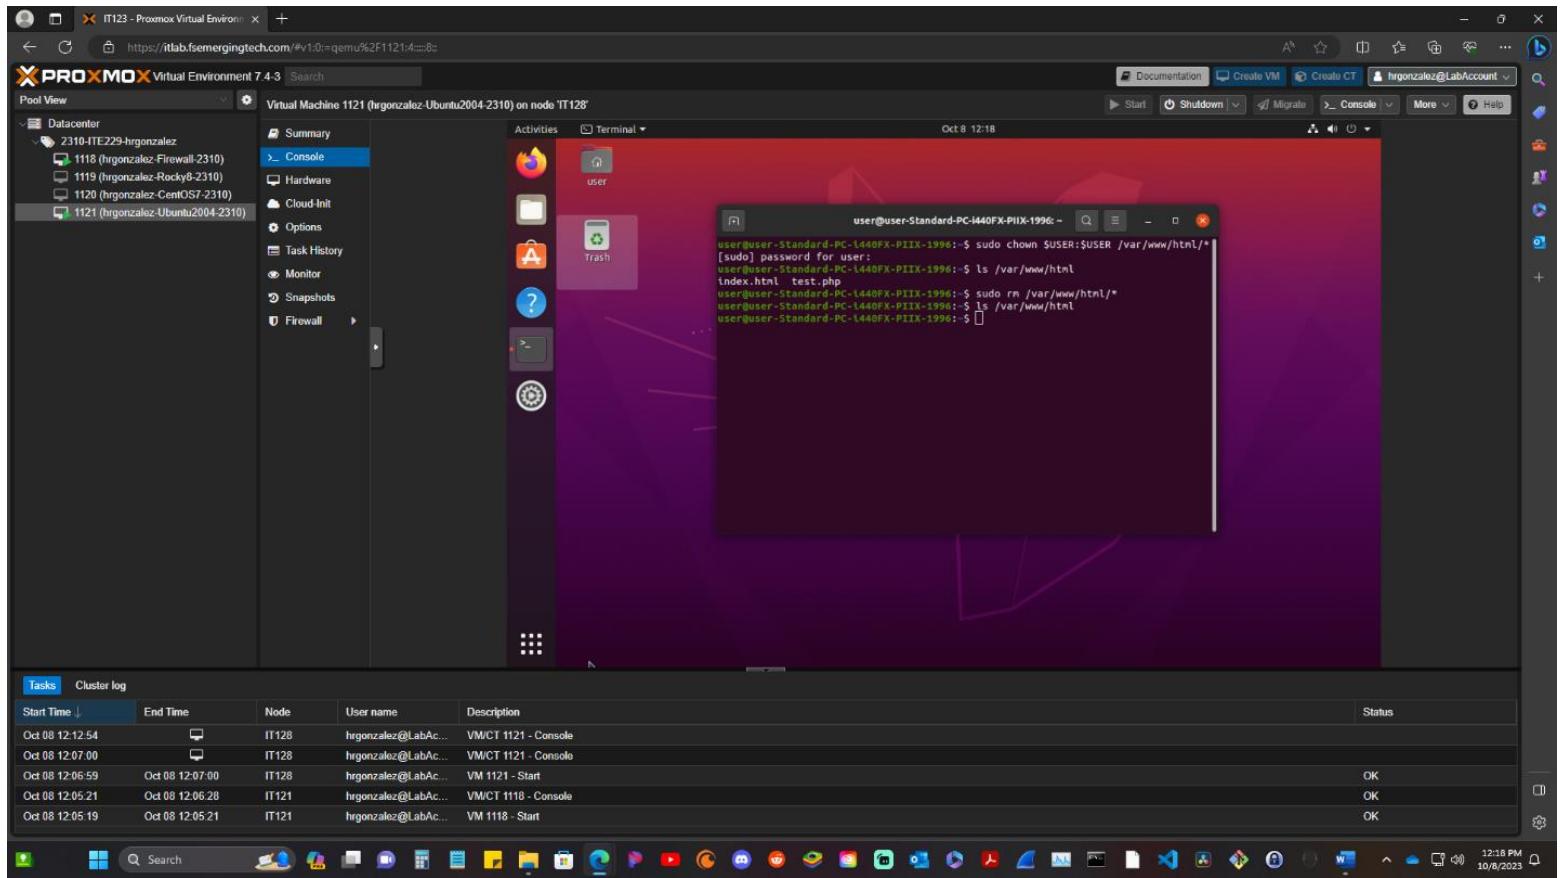

Grant Permission to html Directory to WordPress User

In the Ubuntu terminal enter command line `sudo chown $USER:$USER /var/www/html/*`. This will make sure ownership and group is changed granting permission to all files in that directory.

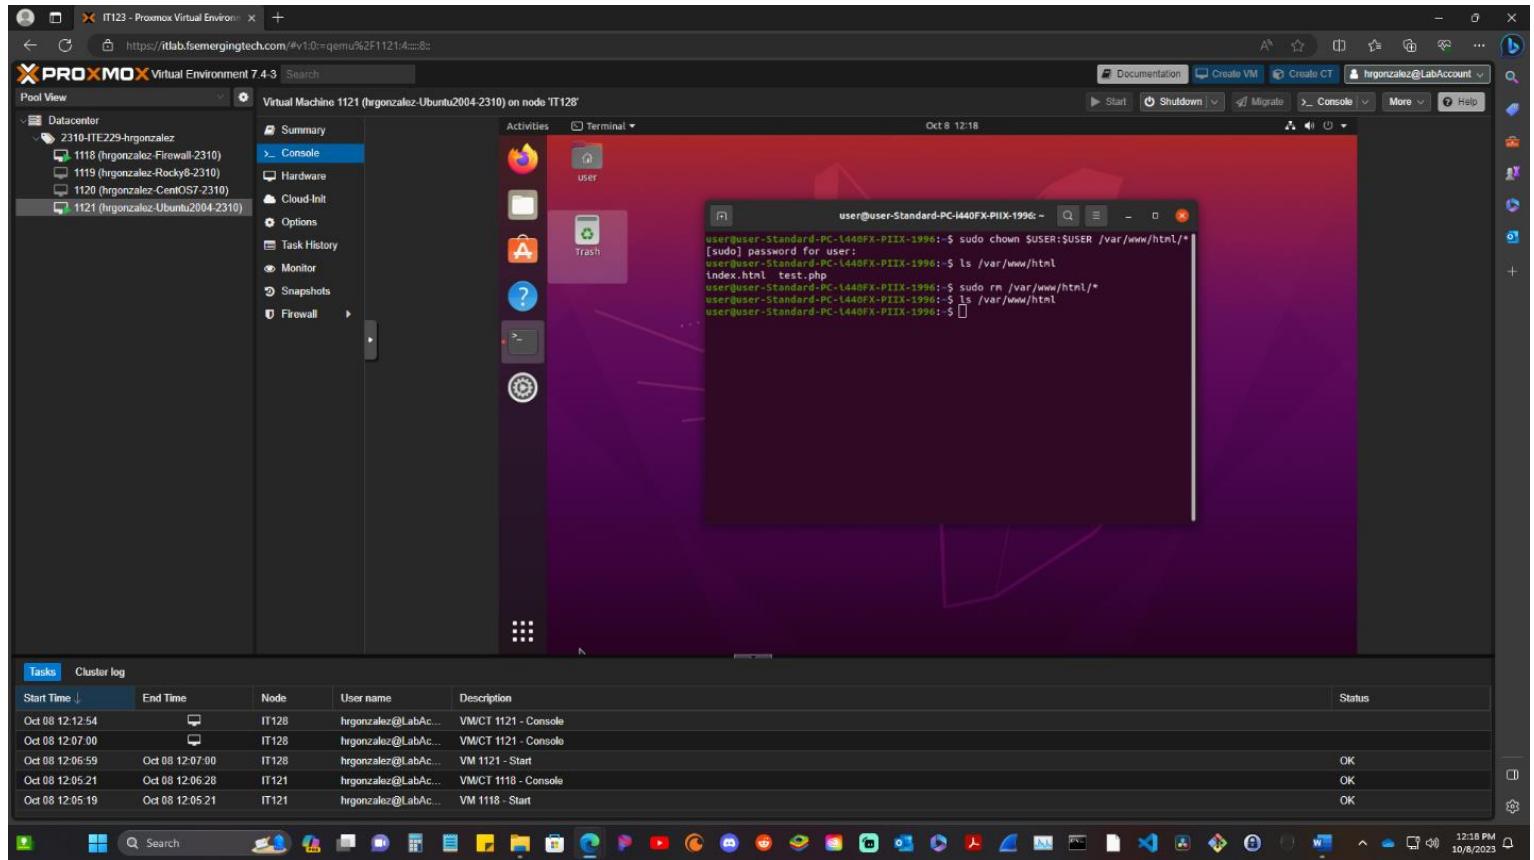

## Delete Files from html Directory

Next we need to delete all files from the html directory. To do this enter command line **sudo rm /var/www/www/html/\***.

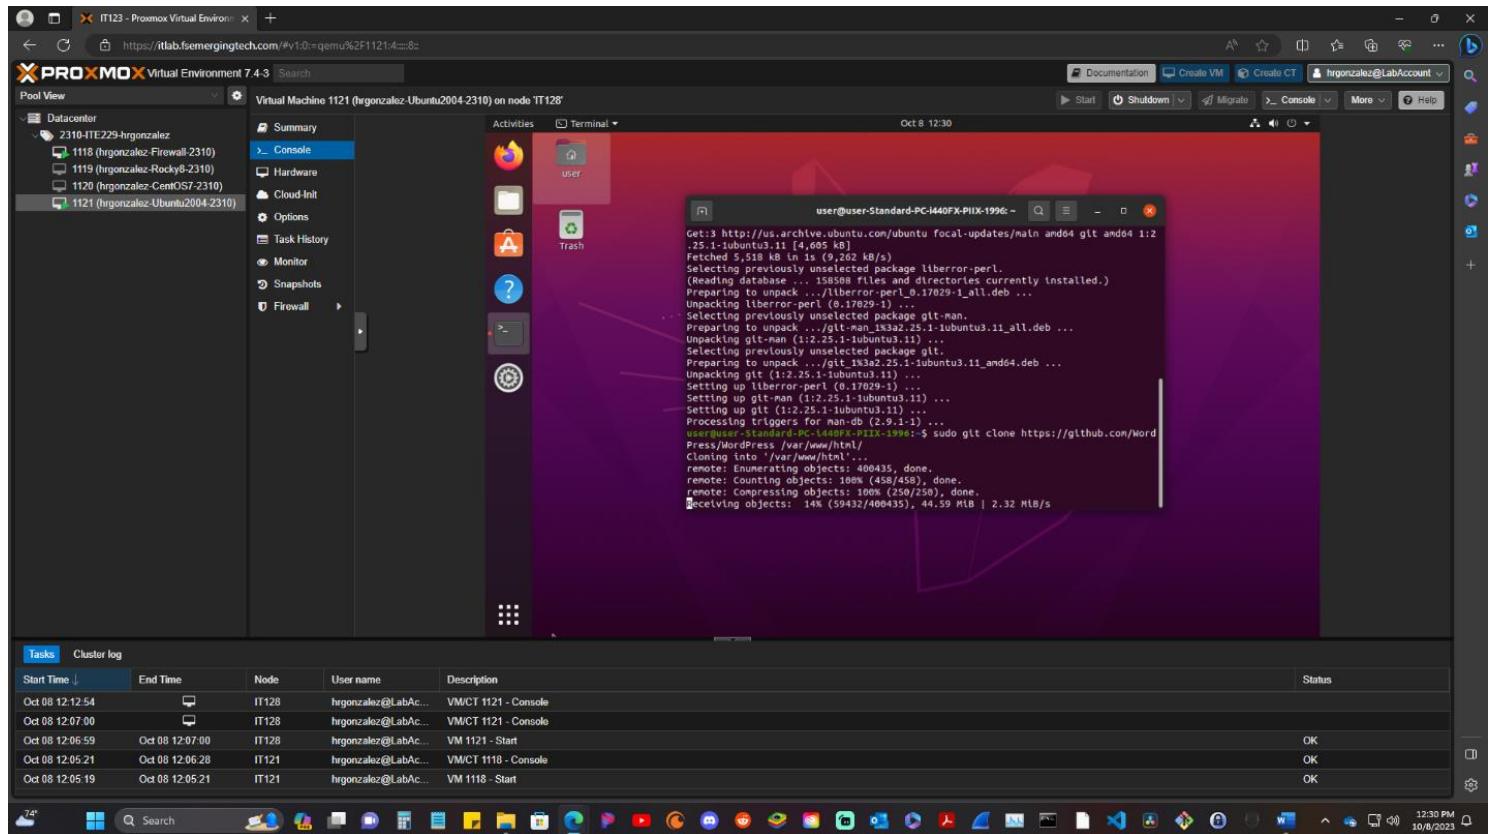

## Verify html Directory is Empty

Now we need to verify html directory is empty by inputting command line `sudo ls /var/www/html/`. This will take us to the html directory and show us the files. If empty it will automatically take you to the username line.

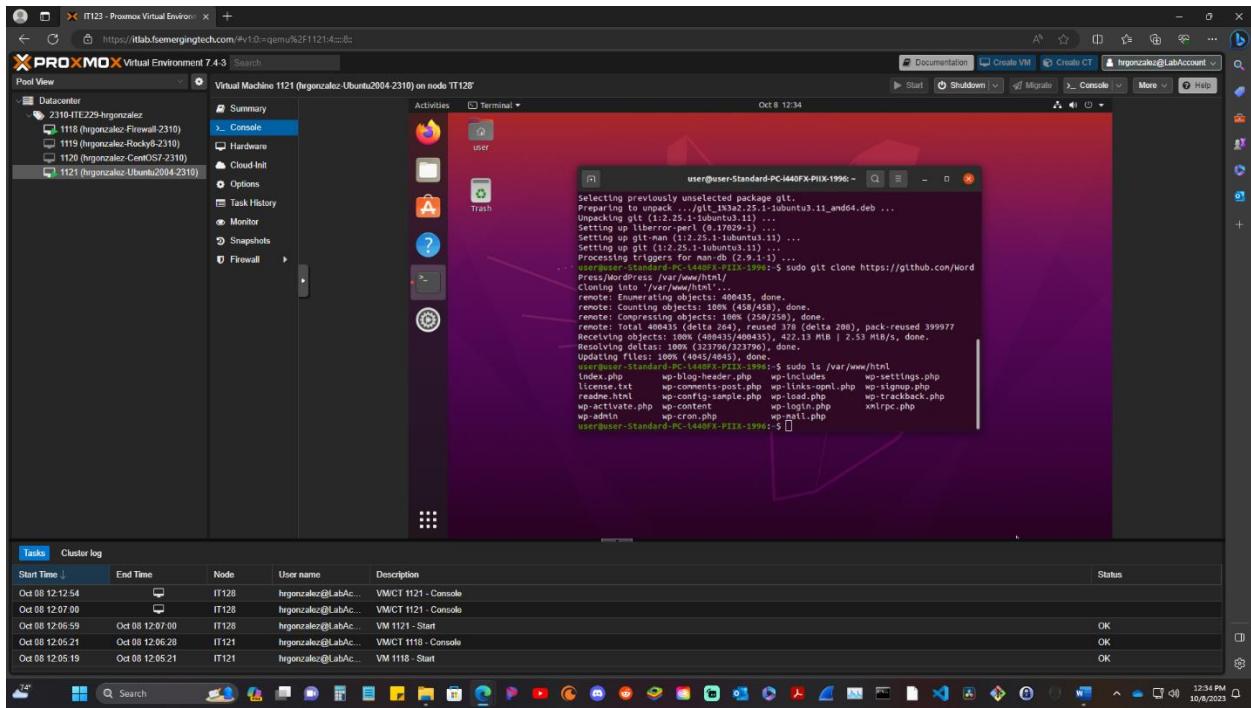

## Clone WordPress to html Directory

Next you need to clone WordPress to html Directory, but first we need to make sure git is installed. Let's input command line `sudo apt install git -y`. If is completed, then it will let you know if not it will undergo the installation process (wait for it to finish). Now we are going to clone WordPress by inputting command line `sudo git clone https://github.com/WordPress/WordPress /var/www/html/`.

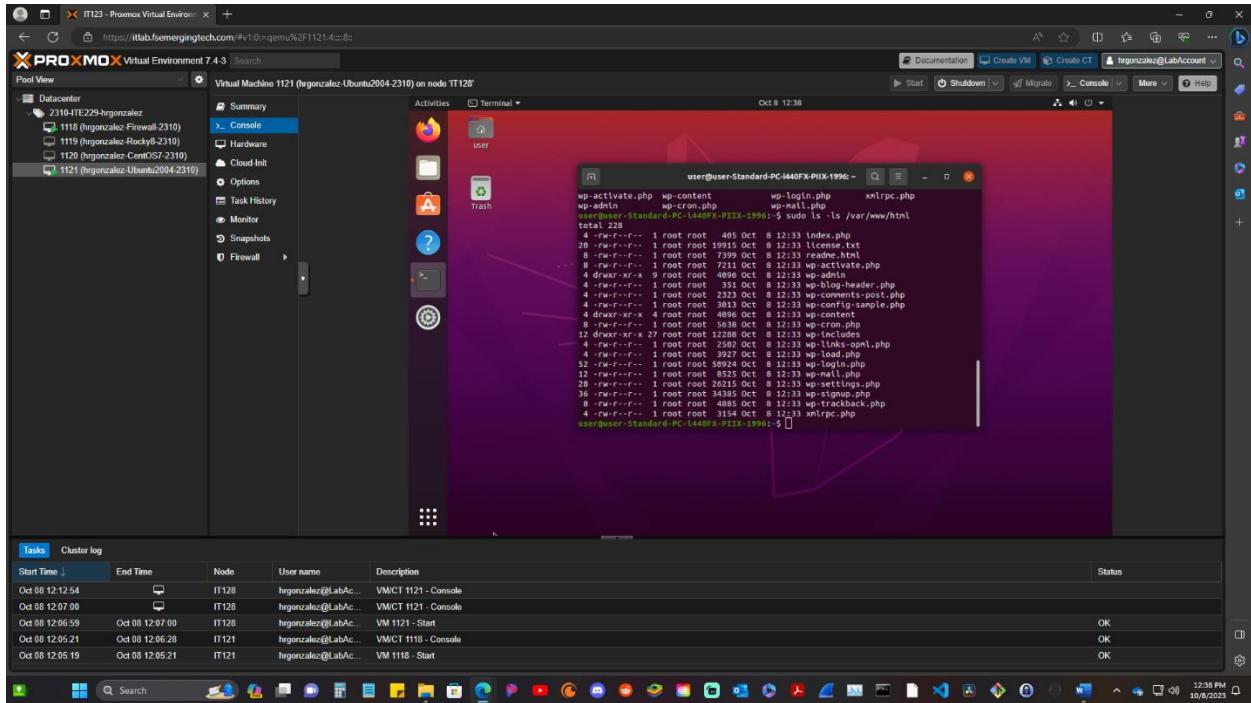

## Verify html Directory Contains WordPress Files

Now we need to verify cloning was successful by entering command line `sudo ls /var/www/html`. You should see all the files in that directory.

## Verify Permissions on html Directory

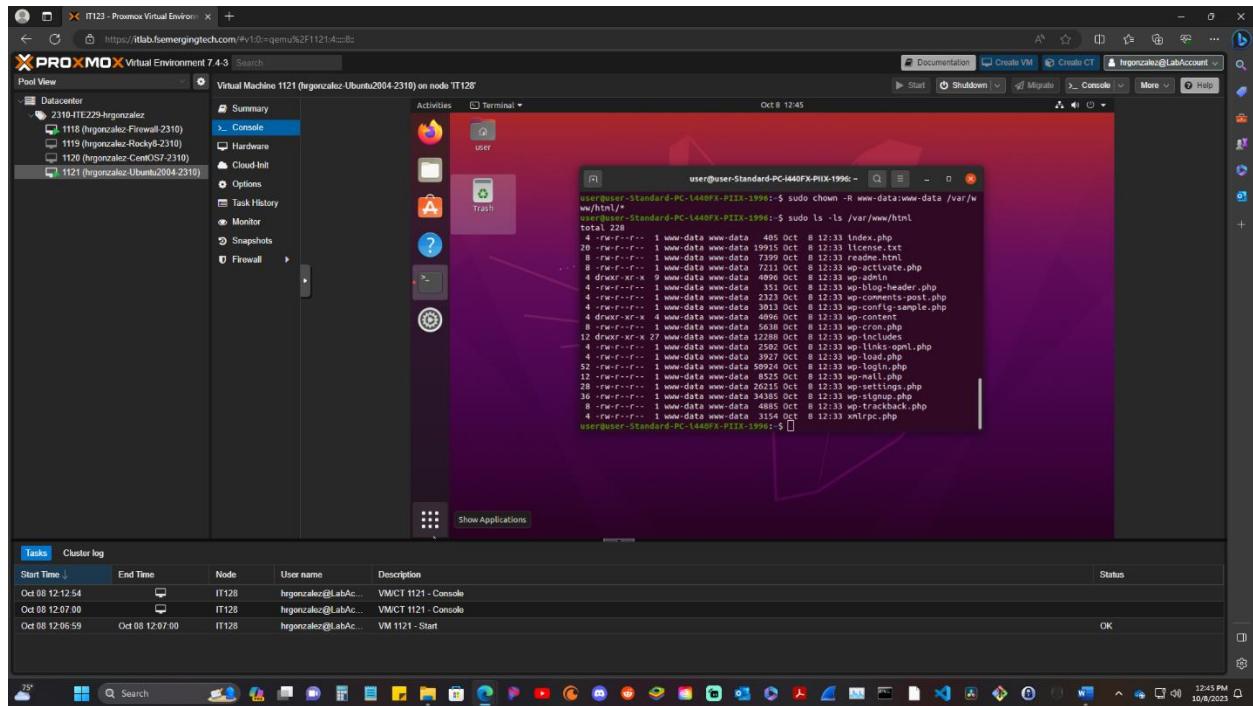

We need to verify our permission on the html Directory. To do this enter command line `sudo ls -ls /var/www/html`. It should look like the picture below.

## Edit Ownership

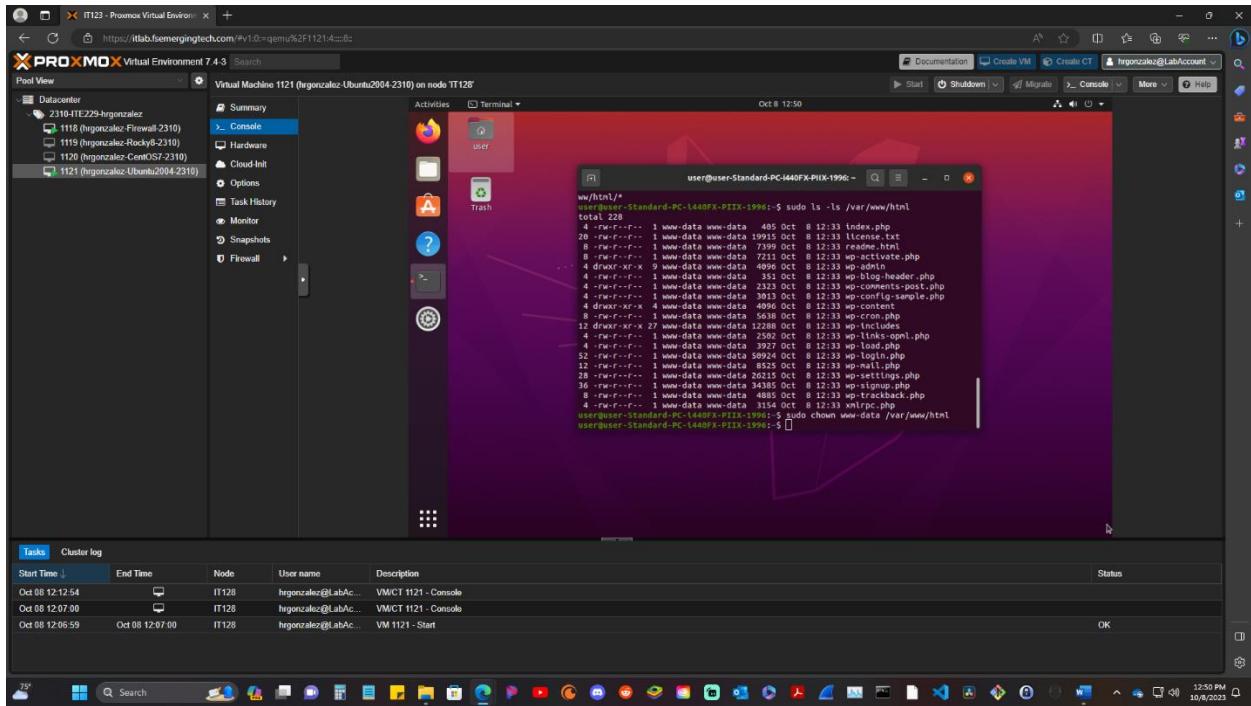

### Edit Ownership of Contents of html Directory

You need to set ownership of the html Directory files. To do this you need to enter command line **sudo chown -R www-data:www-data /var/www/html/\*.**

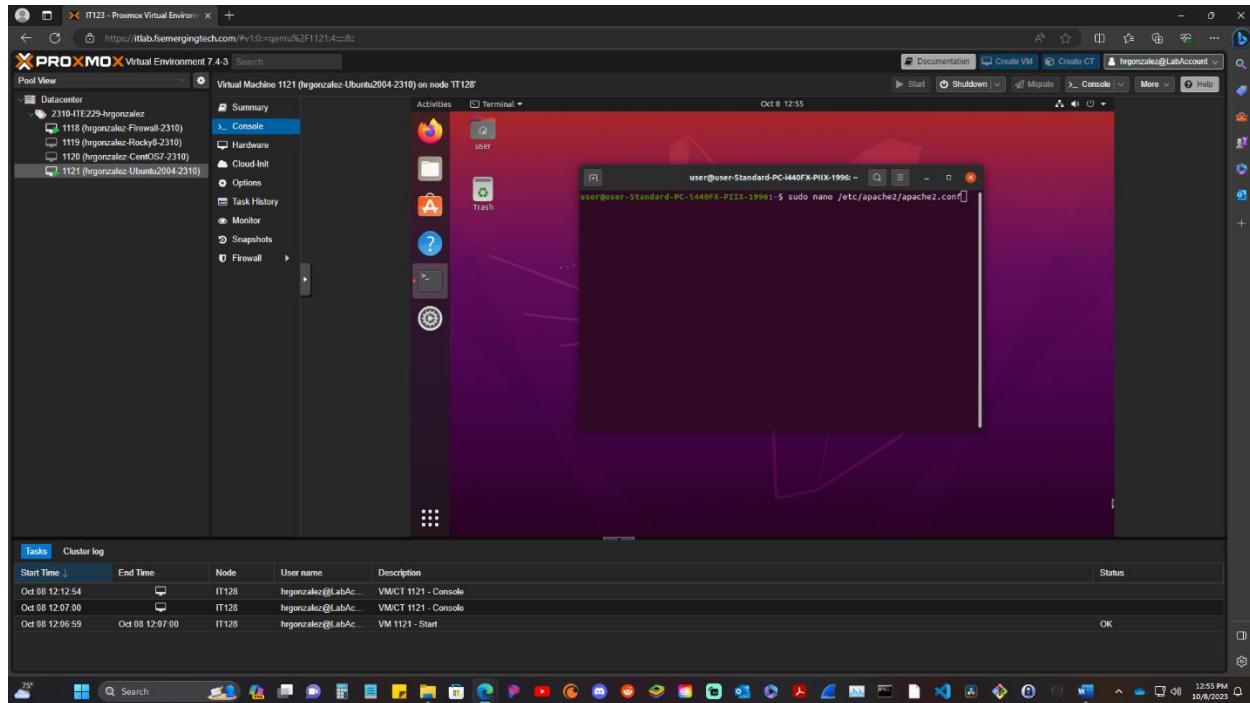

## Edit Ownership of the html Directory Itself

Next you need to change ownership of the Directory itself. To do this enter command line `sudo chown www-data:www-data /var/www/html` it should take automatically do this, and you should be redirected back to your username in the next line.

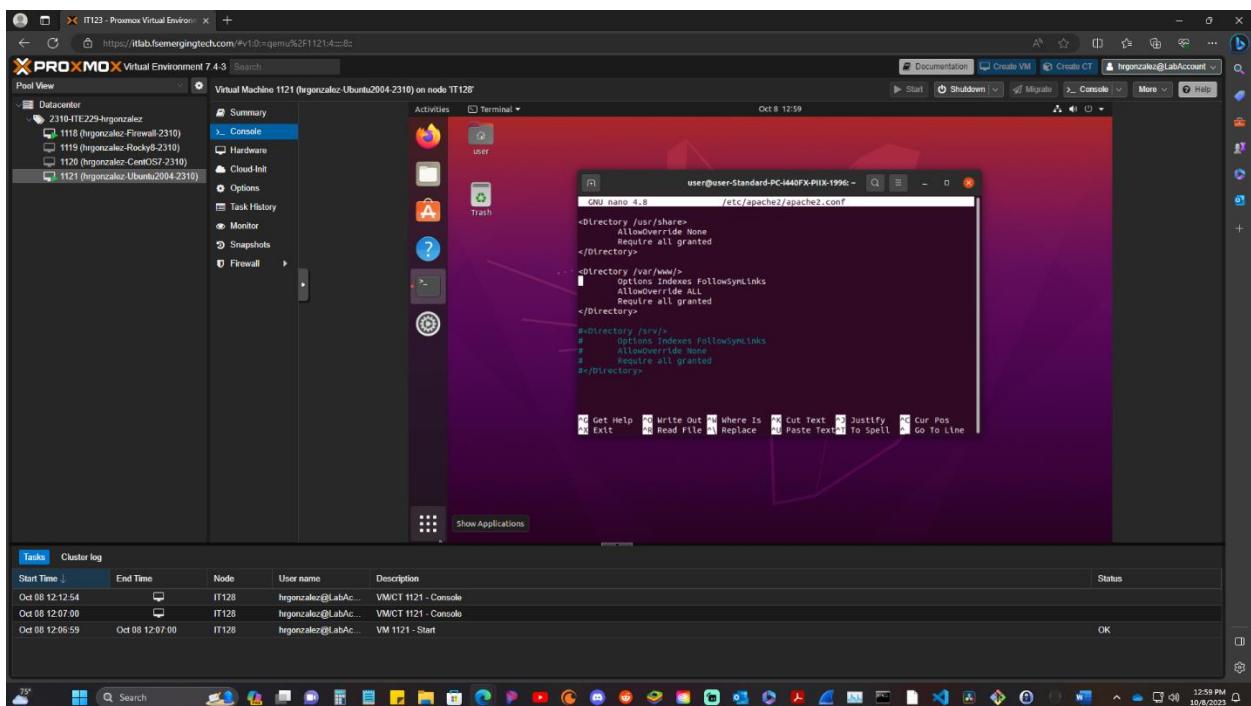

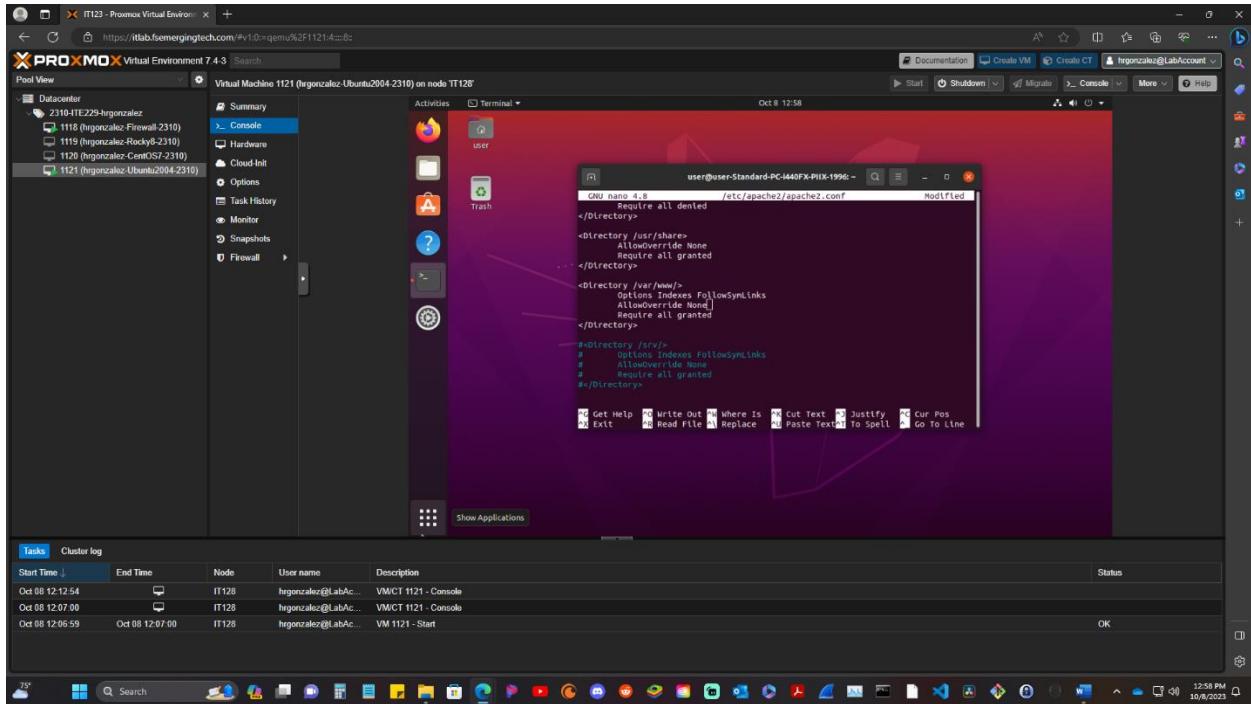

## Edit the apache2.conf File

Next you will be enabling override for /var/www path to enhance security. We need to open the Apache config file. Enter command line **sudo nano /etc/apache2/apache2.conf**.

## Override All Default Apache Directives

Here we need to find locate <Directory /var/www/> and change AllowOverride from None to All. Look at picture below for reference. After changes are made hit control X to exit, saved changes, then hit enter. You should be redirected back to your username.

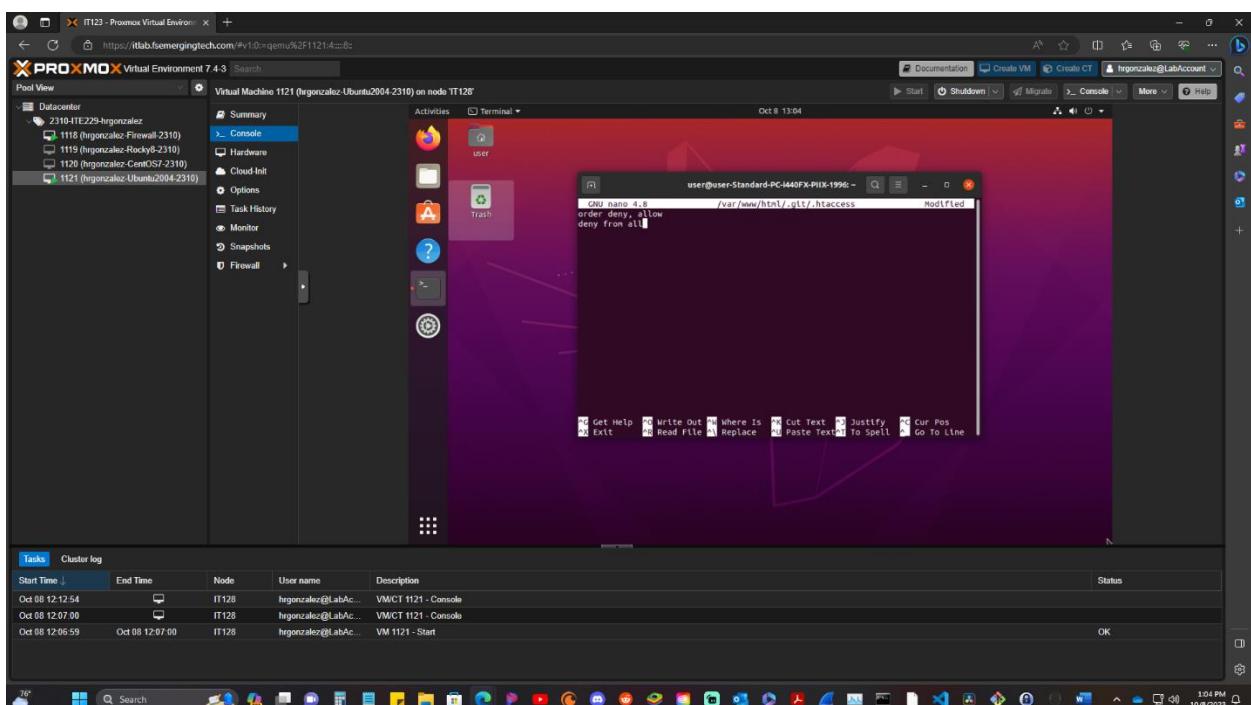

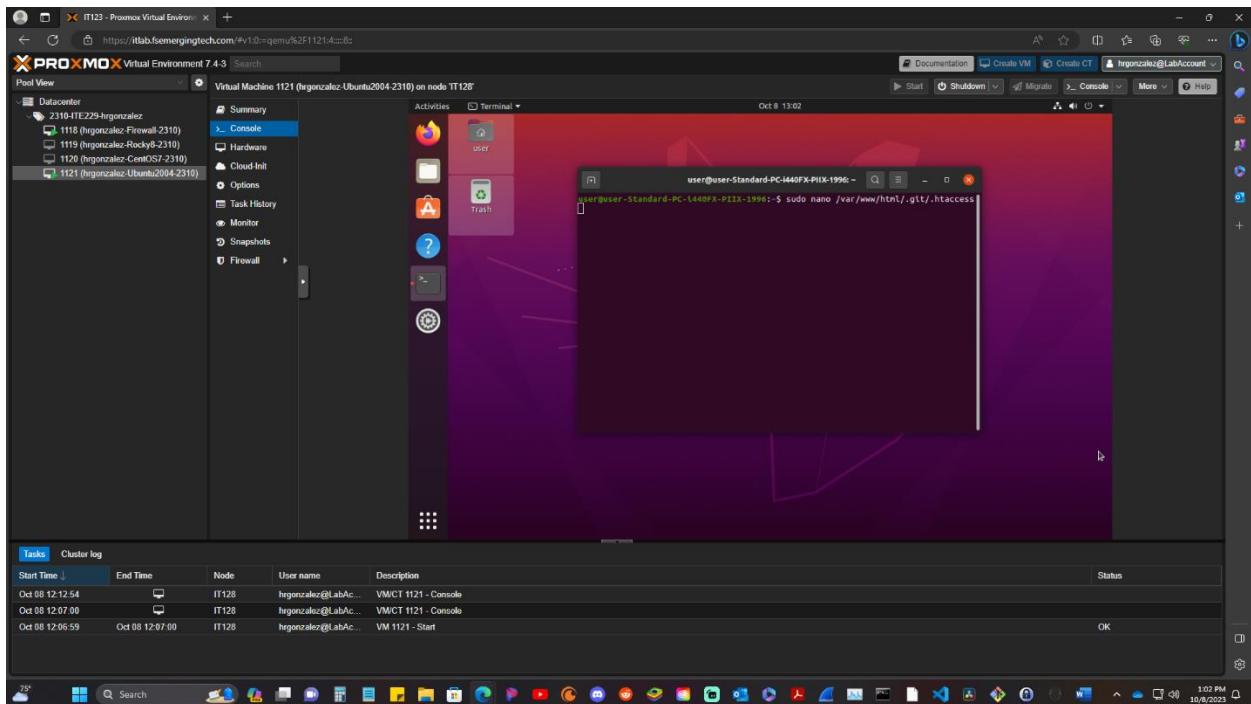

## Create a .htaccess File in the /var/www/html/.git/ Directory

Now you need to secure the .htaccess file under the .git folder to prevent unauthorized users from accessing it. To do this let's enter command line `sudo nano /var/www/html/.git/.htaccess`. Inside nano type: (\*Use picture below for reference)

`order deny, allow`

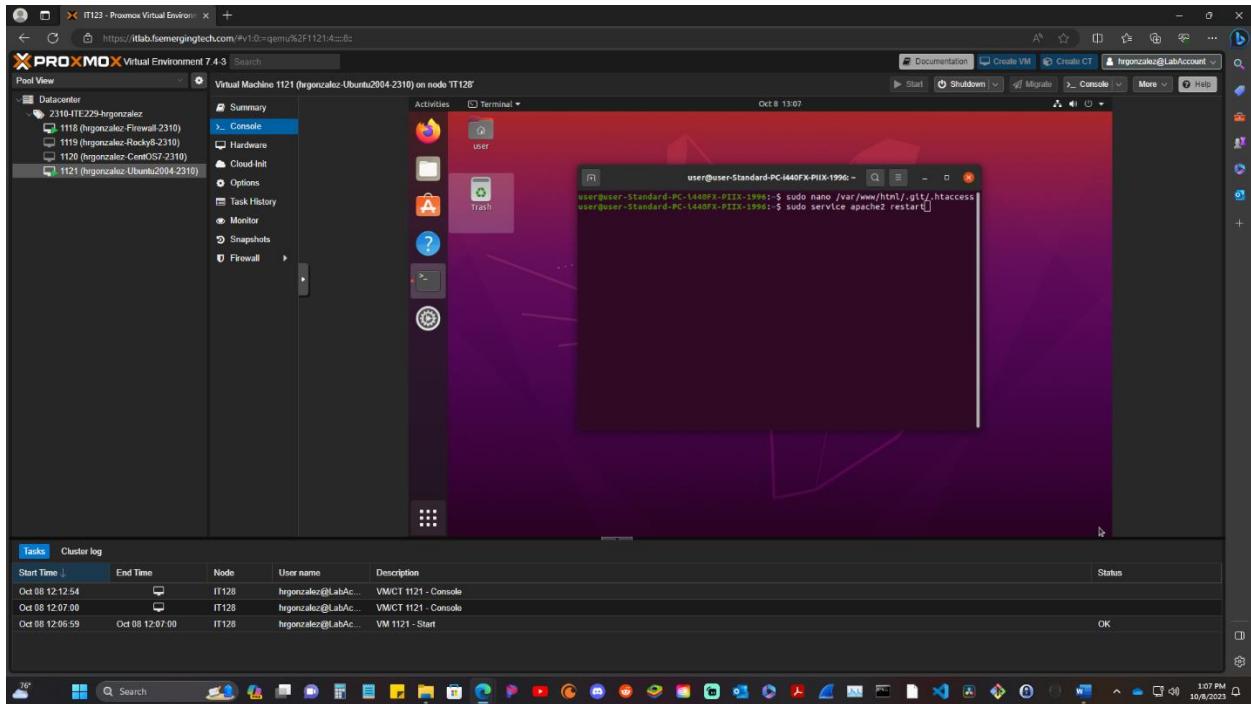

`deny from all`

After hit control X to exit, save changes, then hit enter. It should redirect you back to your username.

## Restart the Apache Service

Now you need to restart Apache Service using command line `sudo service apache2 restart`. This will restart Apache with all the changes.

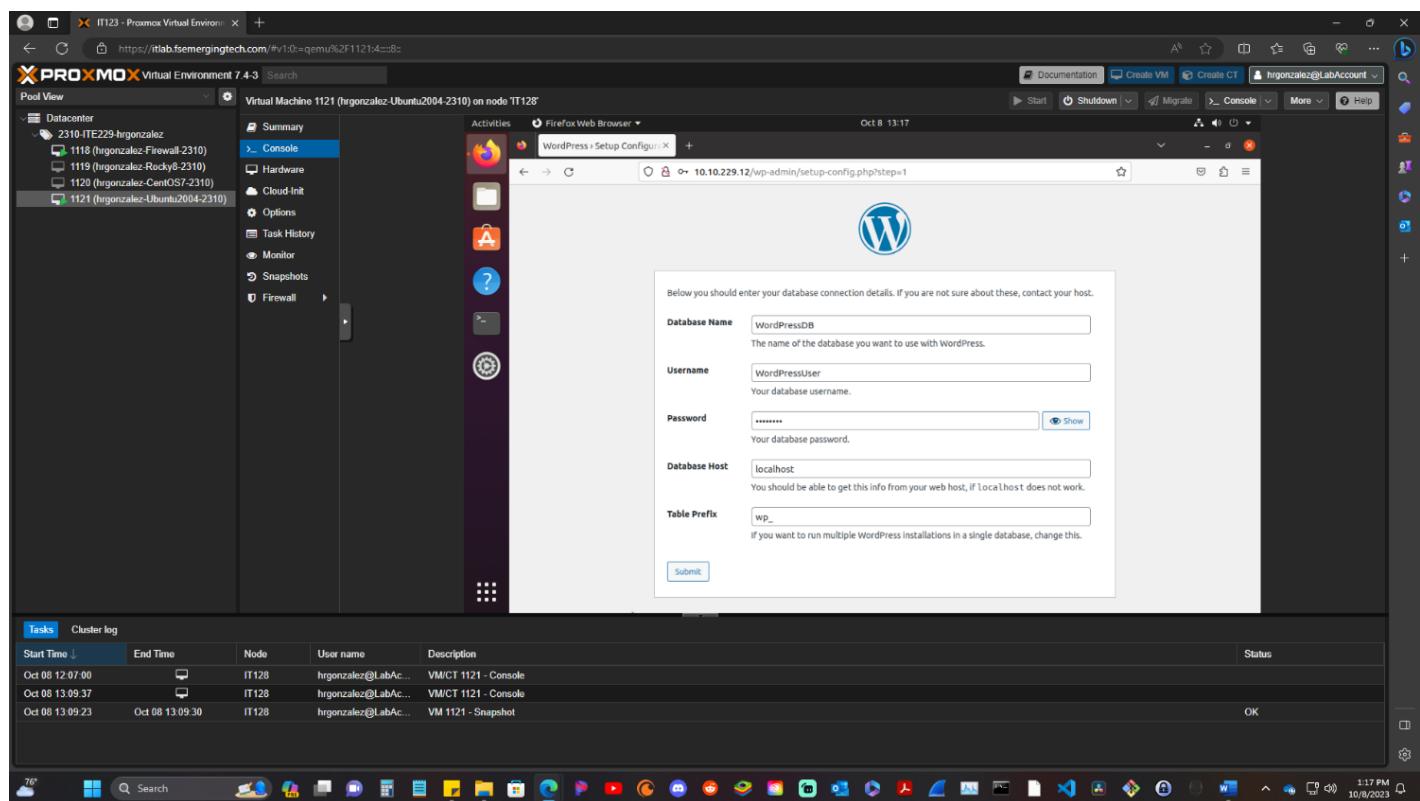

# WordPress Configuration

## Configure WordPress

### WordPress Configuration Selections

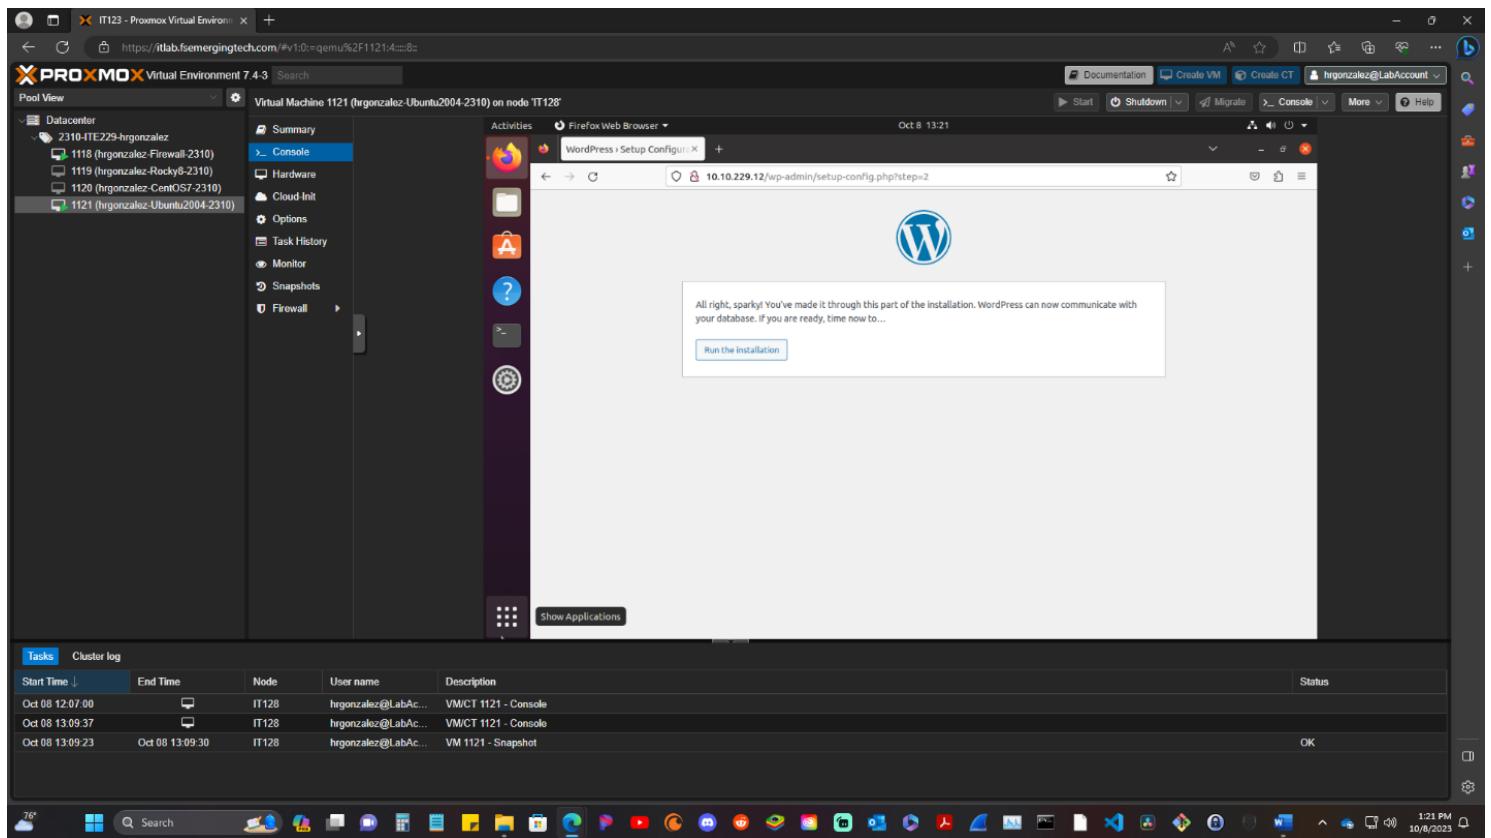

Is time to configure our WordPress site. Using Firefox in Ubuntu enter URL <http://10.10.229.12>. In this page we are going to enter the following information. Make sure all information is correct then hit the submit button.

- **Database Name:** **WordPressDB**
- **Username:** **WordPressUser**
- **Password:** *this is your WordPressUser password*
- **Database Host:** **localhost**
- **Table Prefix:** **wp\_**

## Run Installation

Next you need to hit **run the installation** button.

## Create an Admin WordPress User

### WordPress Site Selections

**Site Title:** Ubuntu LAMP

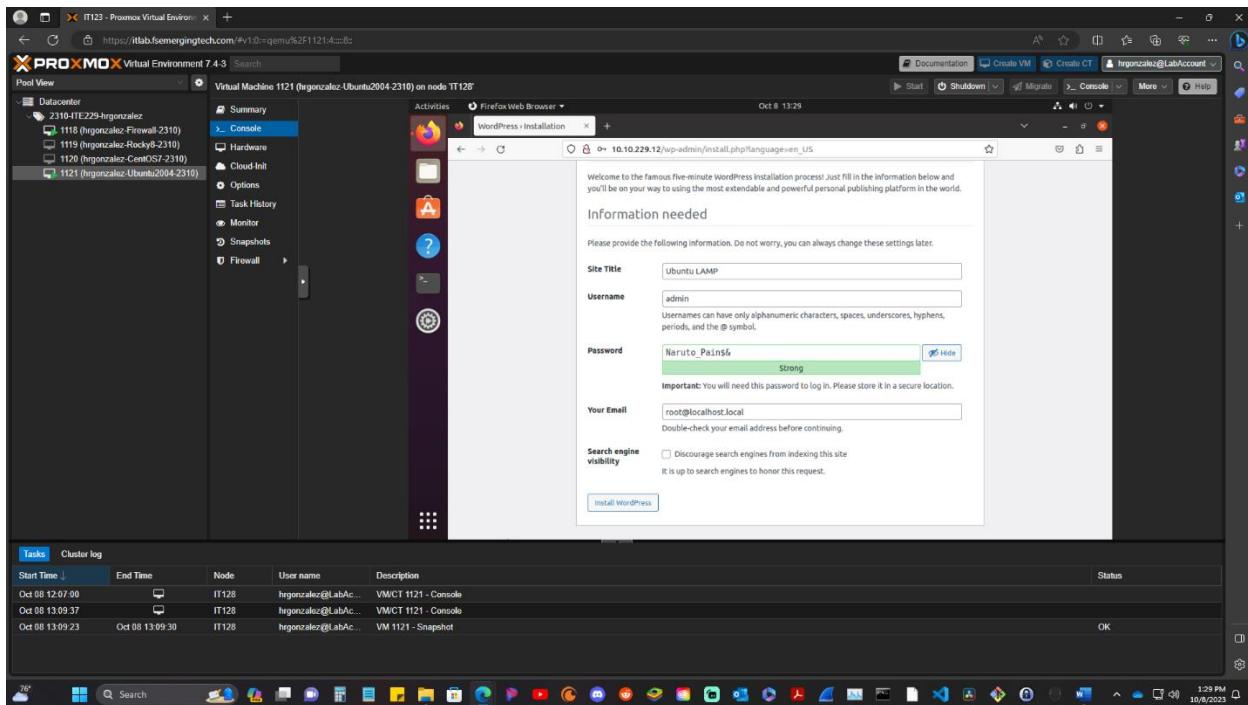

**Username:** admin

**Password:** You will create this

**Your email:** [root@localhost.local](mailto:root@localhost.local)

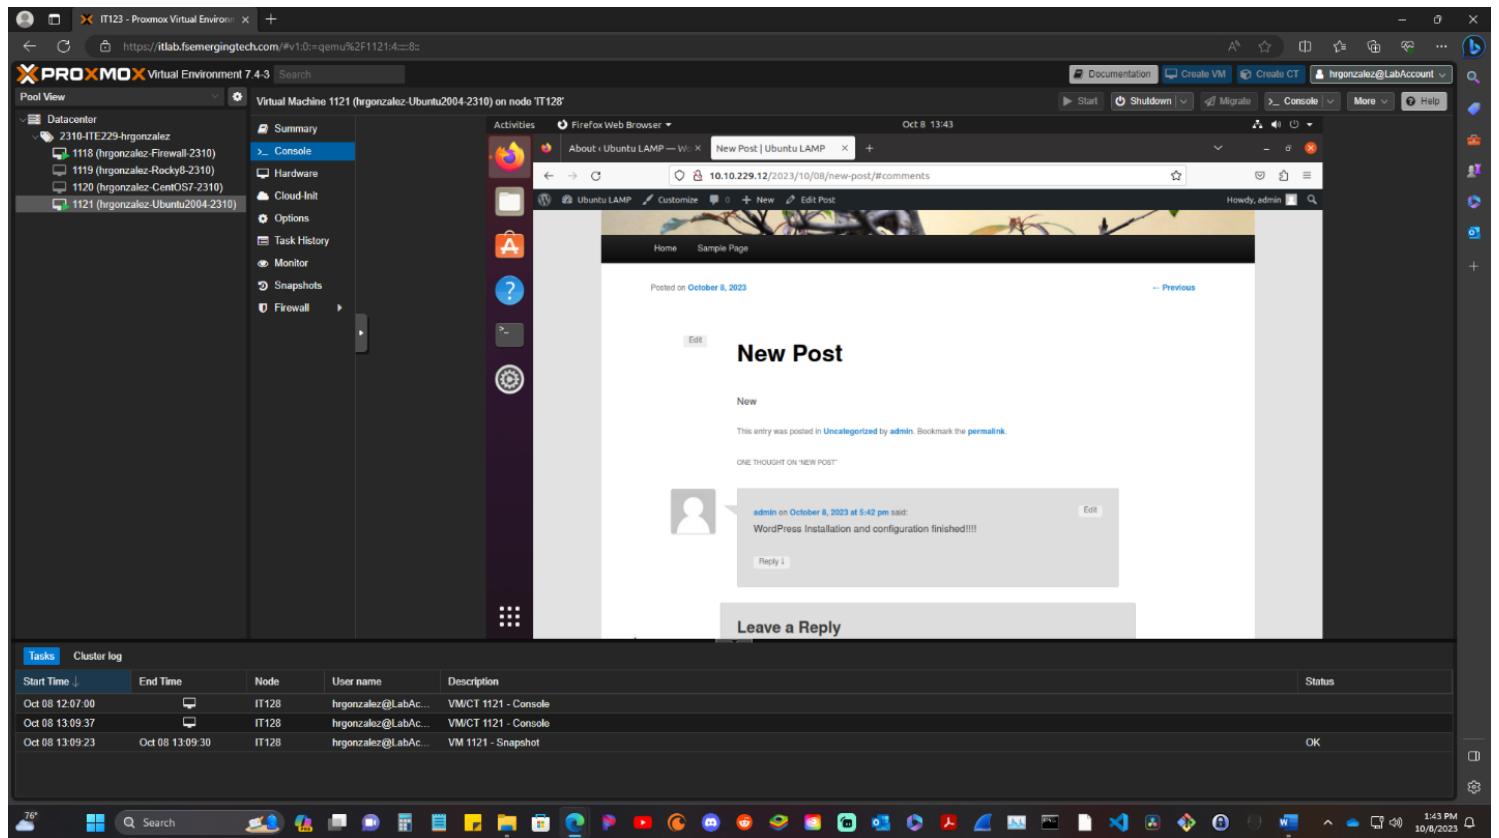

**Search Engine Visibility:** leave unchecked

Let's create an admin WordPress User. In this page we will enter the information provided above. You need to create your own password or use the one that generate it for you (**\*be sure to save this password**). Use the picture for reference. After information is filled in hit **install WordPress** button. It will bring a success page next, here hit **Log in**. It will redirect you to the WordPress log in page.

## Test WordPress

To test WordPress you need to **log in to the WordPress page** by using your credentials. Once logged in, it will take you to the **WP dashboard**. Here you can **make a theme change by hovering over appearance and choose a theme and activate it**. Next you need to **create a post** by **hovering over to post and click all post > Click on Add New Post** in the upper left corner. Type a title and then **New below Title**. Hit **Publish** on the right hand side and **hit publish again**. **Click on the WordPress W** on the left side upper corner this will take you back to the dashboard. Time to test our changes. **Open a new web browser** and in the URL type your blog address **10.10.229.12** and hit enter. You should see your picked theme, title and under it the word **New**. If you see this congratulations test is successful.

# WordPress Security Settings and Configurations

## WordPress Security Summary

WordPress directory (folder) and file permissions is critical for data security and integrity. WordPress relies on a variety of files and directories to work and ensuring that only allowed users and processes can access and modify them is critical. You may prevent unauthorized access, data breaches, and harmful behaviors like code injection by properly defining permissions. Handling permissions inappropriately can reveal critical data, jeopardize the site's integrity, and expose it to attack. Successfully managing permissions is a crucial component of keeping a secure and dependable WordPress website, which greatly helps in the protection of your site's content, user information, and the general performance and reputation of your online presence.

I implemented changes to WordPress site by appointing the right permissions for folders and files within the WordPress installation folder. For the WordPress **admin file** I added an extra layer of authentication. This means that when you log in to WordPress admin website it will redirect you to input a separate username and password redirecting you to the normal username and password then granting you access to the WordPress Dashboard. For the WordPress **content folder** I disable Indexing by creating a security file Options -Indexes. This deny a user from looking into the folder of uploads on our website. As for WordPress **content folder** I went into the upload subfile and created a security .htaccess which denies any php file from being uploaded to that folder.

The **wp-config.php** file in WordPress must be secured since it contains sensitive information such as database credentials, site configuration, and encryption keys. If this file is compromised, an attacker can obtain unauthorized access to your database, change site settings, or introduce malicious code, potentially resulting in data breaches, site downtime, and user distrust. I secured this file by disabling edit themes, plugins, and editing files by implementing a code within the files writable content. I then proceeded and changed the permissions on the file to read only to user, group, and others who have access to the file.

## Defense-in-depth

Securing your WordPress site is absolutely critical, and it all starts with keeping your core WordPress software and all plugins up to date. This step is like ensuring that your home's front door is always locked and secured. Just as you wouldn't leave your door wide open, you shouldn't leave your website vulnerable to outdated software. Moreover, it's essential to maintain regular backups of your site and take screenshots when making changes. This is your insurance policy, safeguarding your digital assets.

In our approach to security at IT & Cybersecurity Solutions, we went beyond simple updates and backups. We understood that strong and unique passwords are a must, but we didn't stop there. We fortified our defenses by implementing two-factor authentication for WordPress. This extra layer of security is like installing a deadbolt lock on your home's front door, adding a formidable barrier to unauthorized access.

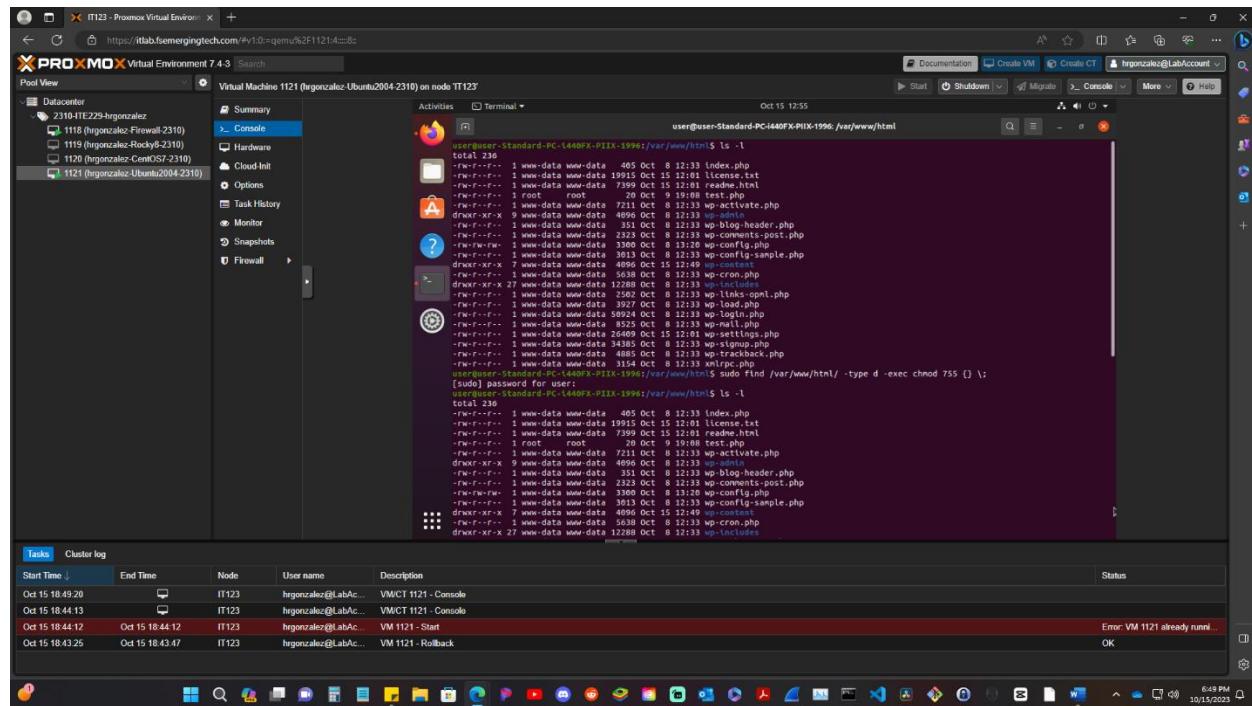

File permissions were another critical aspect of our security strategy. We meticulously ensured that no one could simply walk in and access sensitive files. Installing and enabling the Shield Security plugin was akin to adding a concrete wall between malicious actors and our WordPress site. This plugin not only acts as a defense against digital invaders but also monitors incoming and outgoing traffic, maintaining a comprehensive log of all changes and the overall security level of our WordPress site.

By employing these robust security measures, we effectively constructed a fortress around our WordPress site, making it exceptionally challenging for anyone with malicious intent to breach our defenses. Shield Security serves as our vigilant guardian, ensuring that our fortifications remain solid and reliable.

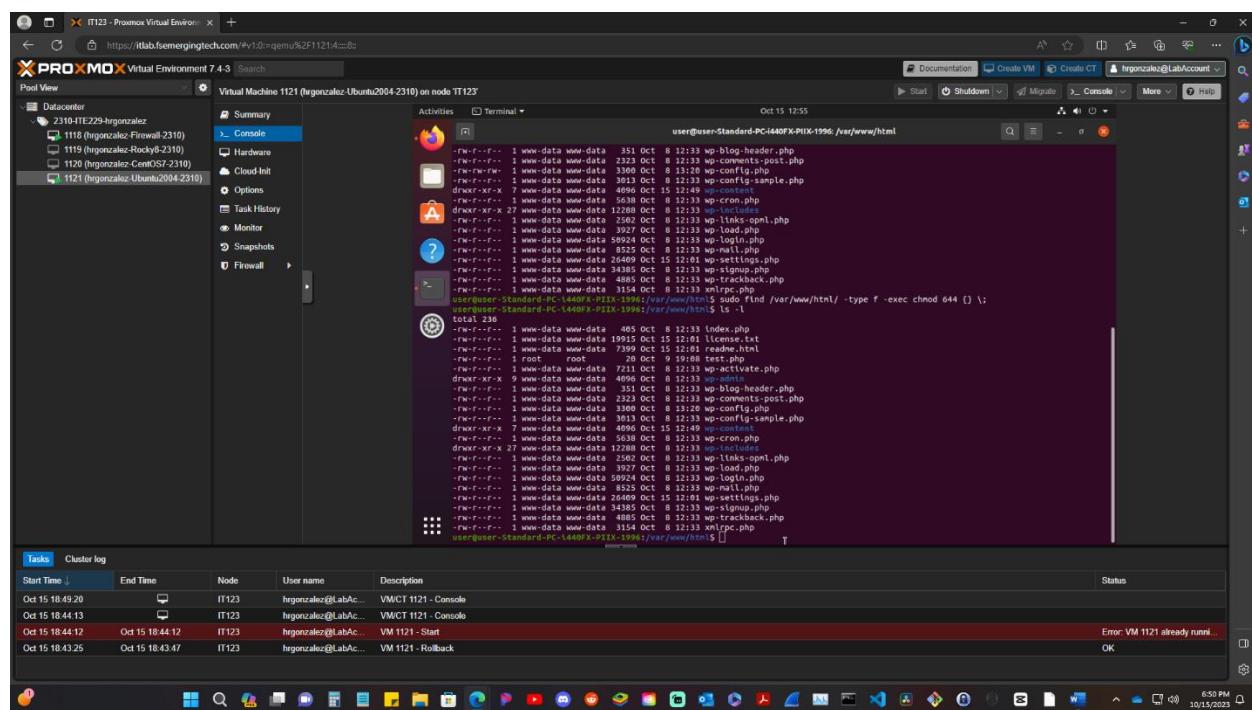

In summary, our defense-in-depth strategy involved the implementation of multiple layers of protection, consistent updates, and continuous monitoring for intrusion alerts. Just as you would take every precaution to safeguard your home, we've applied these principles to protect our digital presence, making our WordPress site as secure as possible.

## File Permissions

### Before Changes

### After Changes

## Vulnerability

File permissions are an important part of computer security, but they can also pose risks if not maintained properly. Overly permissive permissions, which provide excessive access to files and directories, are a severe vulnerability. Malicious actors can easily edit, remove, or inject malicious code into files that are set to be world-writable or have careless permissions in directories. On the other hand, overly tight permissions can prevent genuine users and apps from functioning properly, resulting in compatibility concerns. Incorrect user authorization management can expose sensitive data to unauthorized users.

## Configuration

In order to configure files to meet the proper file permissions for WordPress we went and follow WordPress hardening (hardening- a word for securing further) configuration process. I used the following command:

`sudo find /var/www/html/ -type d -exec chmod 755 {} \;`; this changed the WordPress directory(folder) permissions.

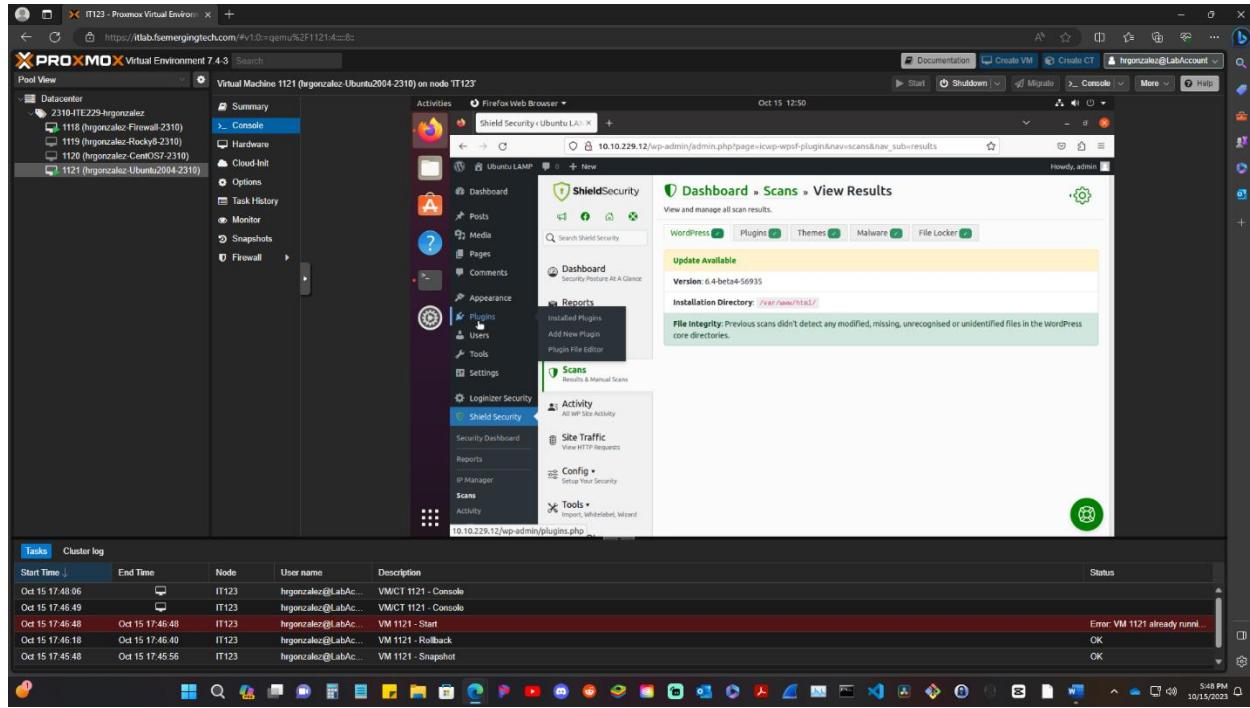

`Sudo find /var/www/html/ -type f -exec chmod 644 {} \;`; this changed permission for files within WordPress directory.

## Validation

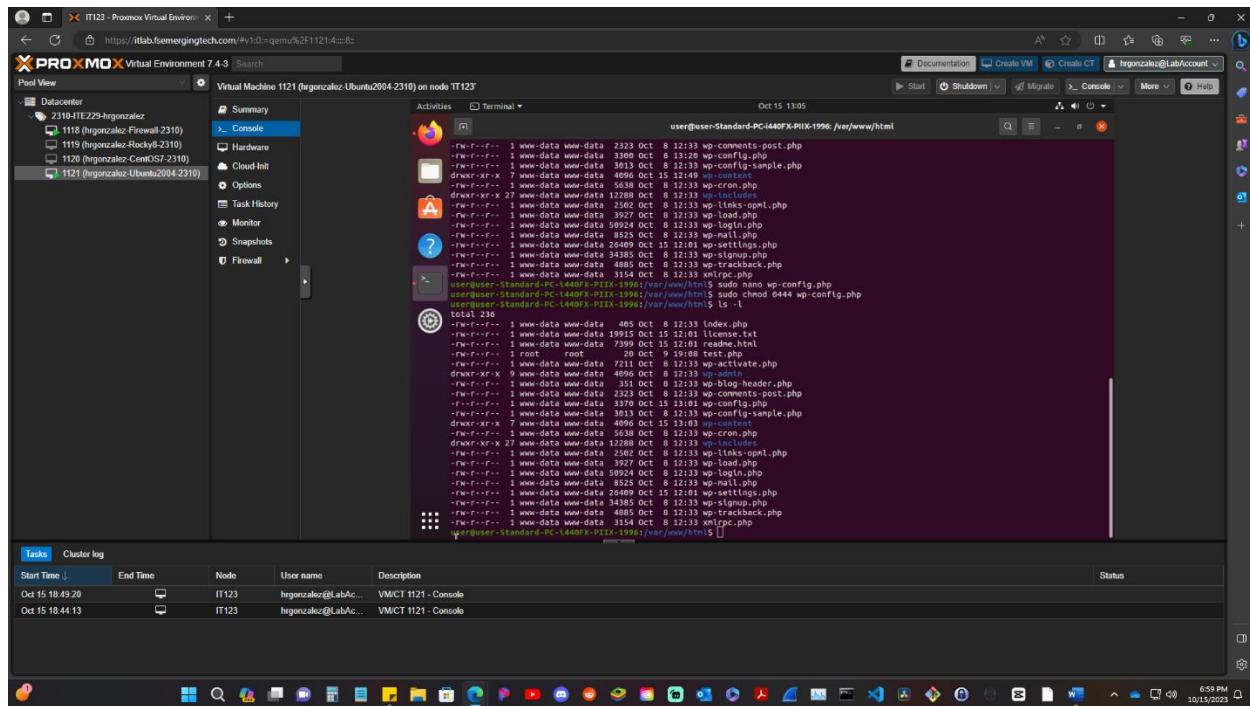

By performing command `ls -l` after the permission changes you can verify permissions and compare from before and after, along with WordPress site permissions to make sure all are correctly configured.

## Securing wp-config.php

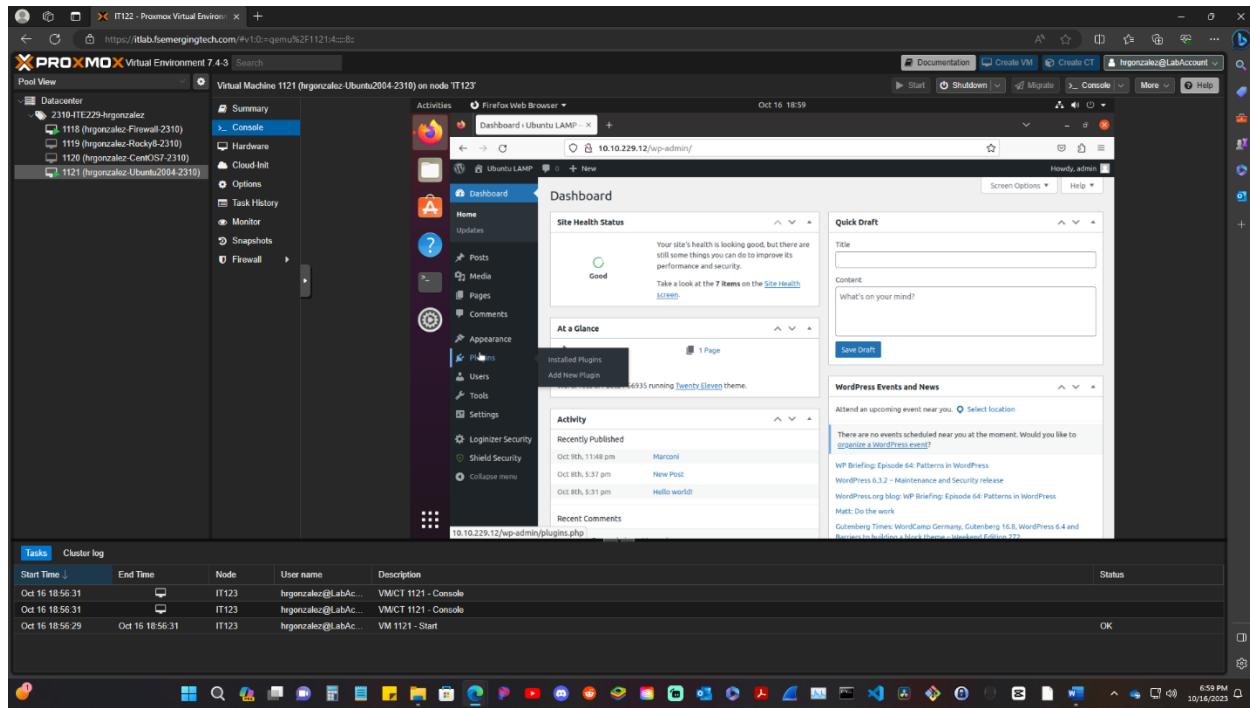

### Before Changes

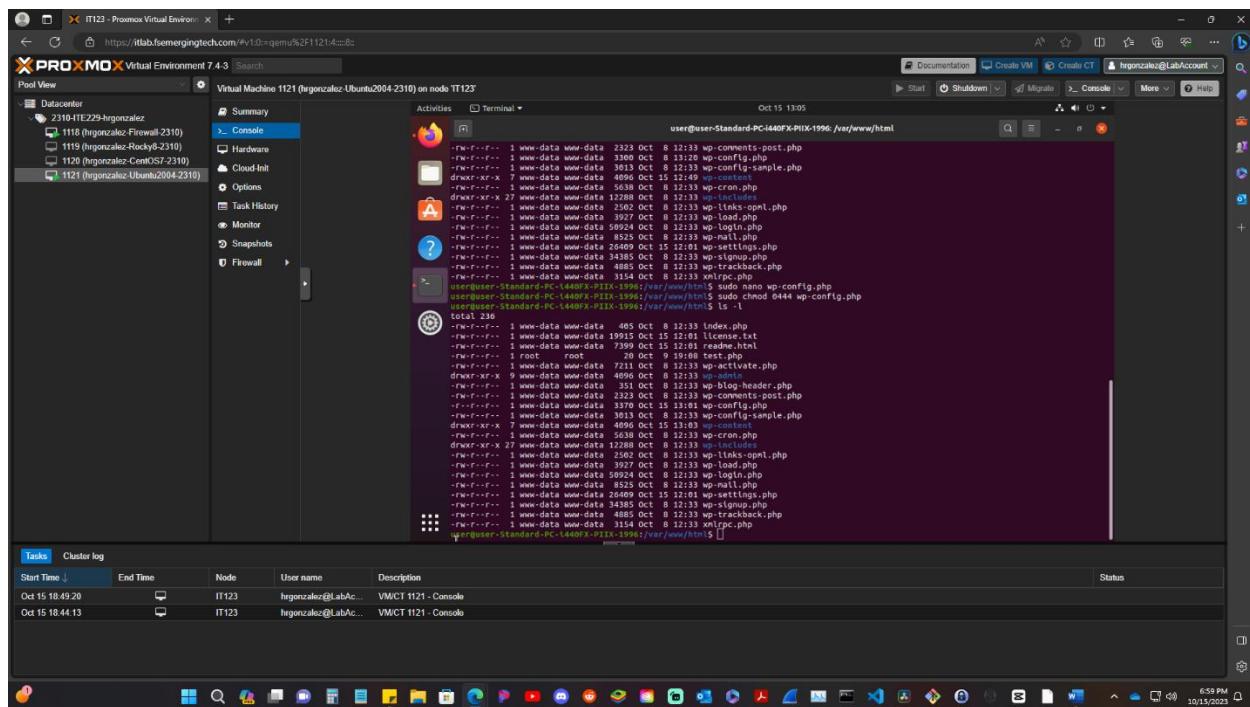

wp-config.php permission displayed on top (above command lines).

## After Changes

wp-config.php permission changed displayed on the bottom after command lines.

## Vulnerability

Unauthorized access is one of the most serious vulnerabilities related with the wp-config.php file. If an attacker acquires access to this file, they will be able to obtain critical information such as database credentials, encryption keys, and authentication salts, potentially leading to a complete compromise of the website. This is especially dangerous because it allows direct access to the site's database, which contains all content and user data.

## Configuration

To meet the file security level of security we made 2 changes to the file. We disable File Editing, and we changed the file permission settings to only read for owner, user, and others. Allowing for two levels of security. Changes were made using command:

`sudo nano wp-config.php` and in the following window scroll all the way down and add context `define('DISALLOW_FILE_EDIT', true);` this will disable edit themes, edit plugins, and edit files in the WordPress admin dashboard.

`sudo chmod 0444 wp-config.php` changes permission of file to only readable for everyone.

\*PS you can also move the file location for a third layer of security.

## Validation

I was able to validate changes by going to WordPress dashboard and making sure edits weren't available. For the permission setting I verified by checking permissions were changed to only read on the file by using command `ls -l` in the directory folder `/var/www/html` and looking at `wp-config.php` file for `r-r` on permission.

## Firewall (Shield)

### Before Changes

The screenshot shows the PROXMOX Virtual Environment 7.4-3 interface. The main window displays the Firewall (Shield) dashboard for Virtual Machine 1121 (hgonzalez-Ubuntu2004-2310) on node TT128. The dashboard includes a summary of security metrics such as Login Blocks, Bot Detection, Offenses, Connection Killed, IP Blocked, and Comment Blocks over the last 7 days. It also features a High-Level System Security Summary section with a large red 'E' icon, indicating a critical issue. Below this, there are sections for WordPress Files (0 results), Malware (0 results), Vulnerable Assets (0 results), and Abandoned Plugins (0 results). The left sidebar provides navigation through various tools like Firewall, Reports, IP Rules, Scans, Activity, Site Traffic, Config, Tools, and Go PRO+. A bottom cluster log table shows recent activity logs.

The screenshot shows the PROXMOX Virtual Environment 7.4-3 interface. The main window displays the Loginizer Security dashboard for Virtual Machine 1121 (hgonzalez-Ubuntu2004-2310) on node TT128. The dashboard shows a list of file permissions for the /var/www/html directory, including wp-admin, wp-includes, wp-config.php, wp-content, wp-content/themes, wp-content/plugins, and .htaccess. The permissions are listed with suggested and actual values. To the right, there is a sidebar with a 'WP Central' advertisement for managing professional pages and content. The left sidebar provides navigation through various tools like Firewall, Reports, IP Rules, Scans, Activity, Site Traffic, Config, Tools, and Loginizer Security. A bottom cluster log table shows recent activity logs.

## After Changes

**Shield Security Dashboard Metrics:**

- Login Blocks (7 days)
- Bot Detection (0 alerts)
- Offenses (0 days)
- Connection Killed (7 days)
- IP Blocked (7 days)
- Comment Blocks (7 days)

**High-Level System Security Summary:**

How good your WordPress site & system security is looking.

## Vulnerability

A WordPress website without a firewall is vulnerable to unauthorized access, brute force assaults, SQL injection, cross-site scripting, malware injections, DDoS attacks, and the exploitation of known or zero-day vulnerabilities. Data theft and file inclusion assaults are also major issues. To mitigate these dangers, it is critical to use a web application firewall (WAF), a security plugin, and to keep WordPress, themes, and plugins up to date. These safeguards are crucial in defending the site from a wide range of security threats.

## Configuration

WordPress hardening website recommends a couple of options for firewalls. We went with Shield Security because is a great plugin firewall for WordPress and it has a great reputation, it's also user friendly. To add this firewall plugin to WordPress all we had to do was [head to plugins](#) and [select add a new plugin](#) in WordPress dashboard. After, we searched for Shield on the search bar and select Shield Security. We activate it and then followed the installation wizard. We [enabled logging](#) to be able to see changes made on WordPress. The great thing is that Shield will automatically scan security level for the WordPress site and give it a letter rating. When we install Shield our letter rating was E and after we harden the system it went up to D. Now other changes can be made in the future to secure the WordPress site even more and bring the rating higher.

We went and install a plugin call Loginizer. We got Loginizer by doing the same steps as above but with Loginizer on search bar. The beauty of this plugin is that it basically shows you on the Dashboard the files that need hardening for WordPress and their recommended permissions. To be able to get the end results we got we just needed to harden the system normally with the exception of the .htaccess file secured. To get this file secured we needed to enter command:

`sudo chmod 0444 .htaccess` this will change .htaccess security file to read only for everyone.

## Validation

By Shield Security changing from E to D it gave me confirmation that Shield Security was working properly and monitoring changes. As far as Loginizer with us making the changes needed during hardening process and securing .htaccess it confirmed everything matched with its recommendation (letter went from red to green or white).

## Conclusion

The security methodology used to reinforce our WordPress website through a defense-in-depth strategy has shown to be a solid and versatile approach to protecting our digital assets. This technique is based on the idea of deploying many layers of security mechanisms, similar to how we secure our homes. This starts with the fundamental yet critical practice of continuously updating both the WordPress core and all plugins, which serves as the digital equivalent of guarding one's front door.

We acknowledged the crucial need of keeping regular backups, which act as our digital insurance policy, protecting our data from potential catastrophes or cyber threats. The use of strong, unique passwords, in conjunction with the adoption of two-factor authentication, adds an extra layer of security, similar to installing a powerful deadbolt lock on our front door. This strategy dramatically improves our security against illegal access. The thorough monitoring of file permissions strengthens our security stance even further, ensuring that illegal access is effectively prevented. The Shield Security plugin, functioning as our digital sentinel, diligently monitors incoming and outgoing traffic, logs any changes, and keeps an overall record of the security state of our WordPress site.

This security methodology is not limited to WordPress, its adaptability may be expanded to various systems and digital environments with ease. The essential concepts of this method remain same whether securing a different content management system, an e-commerce platform, a business infrastructure, or any other digital infrastructure. A solid defense is formed by layering security measures, guaranteeing constant software and system updates, and adopting effective authentication techniques. Furthermore, file permission management and the integration of monitoring systems provide additional levels of protection, guaranteeing that unwanted access is rigorously guarded against.

The defense-in-depth concept emerges as a guiding light for security best practices in our interconnected and ever-changing technological world. By applying this methodology to additional systems, we not only protect our data but also adhere to the fundamental principles of cybersecurity, consisting of Confidentiality, Integrity, and Availability.

# Appendix A

## NginX Config File

```
GNU nano 2.9.8 /etc/nginx/nginx.conf

server {
    listen 80 default_server;
    listen [::]:80 default_server;
    server_name _;
    root /usr/share/nginx/html;

    # Load modular configuration files from the /etc/nginx/conf.d directory.
    # See http://nginx.org/en/docs/ngx_core_module.html#include
    # for more information.
    include /etc/nginx/conf.d/*.conf;

    location / {
        proxy_pass http://10.10.229.11:3081;
        proxy_set_header Host $http_host; # required for docker client's sake
        proxy_set_header X-Real-IP $remote_addr; # real client's IP
        proxy_set_header X-Forwarded-For $proxy_add_x_forwarded_for;
        proxy_read_timeout 900;
    }

    error_page 404 /404.html;
    location = /40x.html {
    }

    error_page 500 502 503 504 /50x.html;
    location = /50x.html {
    }
}

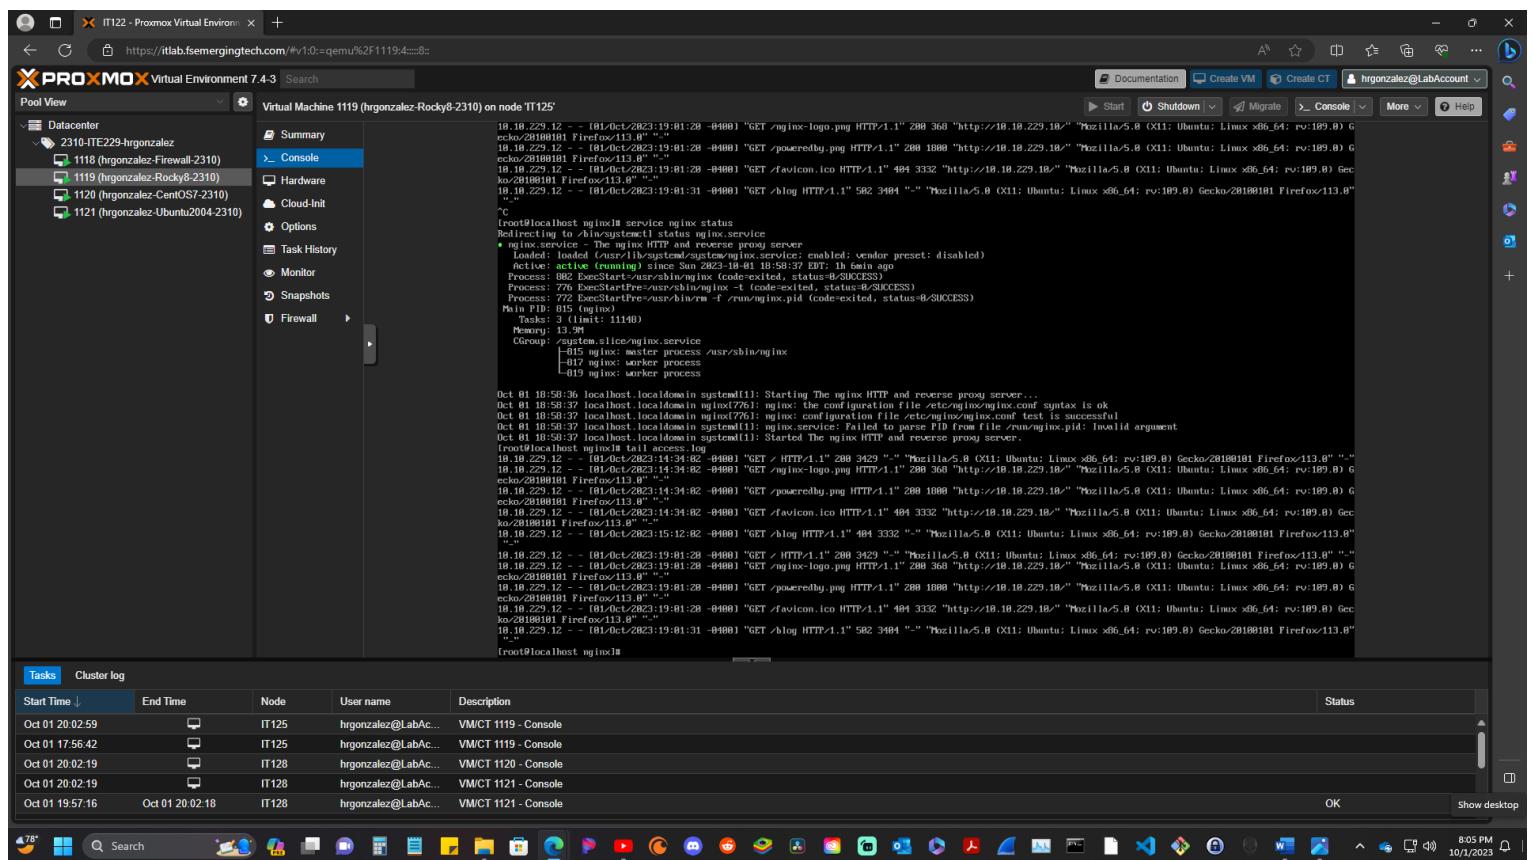

# Settings for a TLS enabled server.
```
